*SCULPTURE.* Sculpture was ordinarily part of the architectural setting which it accompanied symbolically and aesthetically. Never before had there been produced in Europe such an abundance of figural and decorative works in stone, wood, metal and ivory, created by craftsmen organized in guilds. Polychromic treatment of the surface with color or with precious and semi-precious stones is preferred. In subject matter, prevailingly religious or allegorical, Gothic sculpture, in spite of its transcendental attitude, shows more and more the growing naturalism and individualism of the later medieval period. The great statuary programs of Chartres, Reims, and Strassburg may represent the beginning while the statuary of the Burgundian Chartreuse of Champmolle, executed by Claus Sluter († 1406) and his workshop, must suffice to represent the increasing number of individually known masters of the later period. It is the garment draped over the undulating curve of the body which furnishes the expressive material for the sculptor. Its linear traces, its indentations and bulging convexities are treated by each generation, often under the influence of one outstanding masterpiece, in a different manner and allow (based on these evidences in most cases) precise dating and localization. The human body as such was not yet studied anatomically and the nude is avoided in general. And yet, the body is greatly important as the transmitter of generalized aspects of motion and tranquility reflected once over in the naturalistically rendered features of the statue. In its greatest works at the beginning of the Gothic era, a study of Antique statuary (Reims) enhances the "classical" characteristics. Yet from decade to decade, the distance from antiquity becomes greater and the blend of realistic details with an idealized and abstracted curvilinear style results in the unique Gothic expressiveness. The 15th cent. shows an ever growing amount of realism paralleling a similar tendency in Italian Renaissance sculpture of the same period. Sluter (works in Dijon from 1390 to 1406), the Dutch Gothic master, and Quercia (1374-1438), the contemporary Italian sculptor, half Renaissance and half Gothic in his style, must be understood as exponents of one trend. The latest phase of Gothic sculpture from about 1480-1520, is characterized by mannerism, expressionism and sentimentalism, showing a rich production especially in Germany (Leinberger (active 1510-30). Notke (1440-1509), Riemenschneider (1460-1531) they all are indicative of the refinement and sometimes the decadence of the latest phase of the Gothic style.

While Gothic sculpture may be studied today in most of the American and European museums, it reveals its intrinsic beauty only if connected with its original architectonic setting. England and the Central European countries (better than France which, with some glorious exceptions, has suffered from the devastations of the French Revolution) can reveal in its churches, city halls, fountains, etc., the decorative and symbolic function of Gothic sculpture.

*PAINTING.* Mural painting and miniature illumination appear as the two poles of monumental and of intimate recording in our period. Between them a new type slowly rises: easel painting. It takes care of the increasing number of orders for altar panels, painted crucifixes, memorial images, etc. The technique applied is tempera with its opaque quality until the brothers Van Eyck (ca. 1370, Jan died 1441) at the beginning of the 15th cent. introduce the richer oil medium and with it a new luminosity and transparency. The subject matter as well as the purpose of Gothic painting is prevailingly religious. It teaches the Christian dogma from the walls of its cathedrals, it illustrates the story of Christ and his Saints in manuscripts and it visualizes it on altar panels. Yet also there is the beginning of profane illustration as we find it e.g. in the political admonitions of the Palazzo Publico in Siena, painted by Ambrogio Lorenzetti (1337-1339). There are manuscripts with calendar illustrations, medical treatises and since the 15th cent., moralizing interpretations of Antique authors (c.f. *Ovid moralisé*) which widen the circle of pictorial representations. However, nothing bespeaks more the spirit of rising individualism, so closely connected with the introduction of easel painting, than the appearance of portraits. In the French-Burgundian court atmosphere, we must look for its beginnings (portrait of Jean le Bon, 1350-64, Paris, Bibl. Nationale). With

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

the Van Eycks in the North and the first Renaissance masters in the South (Masaccio, Uccello, Domenico Veneziano, Pisanello), portraiture becomes universal early in the 15th cent.

The characteristics of the new style, derived from Gothic statuary with its S-shaped curves and gentle individualism, appear first in French and English miniatures around 1200. Monastic scriptoria and transportable tapestries help to spread the new style. Gothic painting begins as a flat pattern design on abstract gold or ornamental background but takes on, at the end of the 13th cent., a vigorous trend toward three-dimensional space, naturalistic details and psychological individualization. All these elements appear combined and powerfully realized in the art of Giotto (ca. 1276-1337), whose works establish new standards for European art. From Siena, these characteristics, slightly modified and in a more lyrical manner, are transferred by Simone Martini (ca. 1283-1344) to Avignon, the residence of the popes in exile. From there the new style spreads eastward and westward, blending with the local Gothic idioms of France, Germany, England, etc. In the second part of the 14th cent. new impulses from the Northern Italian followers of Giotto bring about the flourishing of an influential Bohemian group, centered in Prague, then the crownland and residence of the German emperor. It is a truly "international style" which dominates Europe from the beginning of the 13th cent. However, painting does not acquire the dominating place in the field of medieval arts before the 15th cent., and this is the time when the international Gothic (which really is a French one, nationally modified) divides itself into its individual national components. The greatest impulse radiates now from the Burgundian-Flemish countries. Out of the germ of illustrative miniature painting, as fostered by the Dukes of Burgundy for their prayer books (*livres d'heure*), grows the new realistic landscape painting, the portraiture and the intimate devotional easel paintings of Hubert and Jan Van Eyck, the founders of the Flemish school, of Rogier van der Weyden [after 1400-1464], Hans Memling [ca. 1430/40-1494], Hugo van der Goes [died 1482].

From this time on the Central European countries follow the line of late Gothic naturalism and expressionism for another century, while Italian painting thrives under the sun of its classical-Mediterranean revival in the Renaissance. Around 1500, the Gothic comes to an end in the North greatly under the influence of Italian form and aesthetics. Albrecht Dürer (1471-1528) from Nürnberg, brings the classical message to the Cisalpine countries. At the same time, the mediaeval world seems to burst forth in one glorious mystical finale in the Isenheim altar (now Museum, Colmar) of Mathias Grünewald (died ca. 1530).

In the 16th cent. and even in the 17th cent., certain elements of Gothic church architecture survive in Germany, Belgium and England as a Post-Gothic resisting in the native tradition the ever increasing thrust of the Italianate Renaissance, Mannerism and Baroque. (The artificial revival of the middle of the 18th cent., originating in England, is discussed under Neo-Gothicism). See MEDIEVAL CIVILIZATION: Coulton, G. **Gothic notation.** See NOTATION.

**Gothic novel.** See NOVEL.

**gouache.** A type of water color painting made with opaque water colors. A pliable adhesive is usually added to the binder to give the surface a soft sheeny quality and to make the paint dry more slowly. —R.L.W.

**gourd shape.** A form often seen in oriental art which simulates a true gourd.

**Gouro art.** See AFRICAN NEGRO ART.

**grace.** *Mus.* A vocal or instrumental ornament not essential to the melody or harmony (grace note).

**gradation.** A gradual passing from one tint or shade to another. *Mus.* A diatonic succession of chords.

**grade crossing.** See CIVIC PLANNING.

**gradine.** A toothed chisel.

**gradual.** See MEDIEVAL MUSIC; Mass.

**gradual responsorium.** See MEDIEVAL MUSIC.

**graffito.** See sgraffito.

**grain.** *Book.* The arrangement or direction of the fibres, etc. in paper, the warp in cloth, the texture in leather. To dye in "grain" is to dye deeply. Graining cloth or leather is done in a variety of ways; by rolling between rollers with an engraved grain on the one; by pressing between flatplates; or by hand with a cork-covered board, sometimes termed **boarding.** —H.E.S.

**grain of rice porcelain.** See CERAMICS II.

**gramophone.** See phonograph.

**Granada ware.** See CERAMICS II.

**granary urn.** In oriental art, a cylindrical covered earthenware receptacle with overhanging cover somewhat resembling a granary.

**grand adagio.** See adagio (2).

**grand opera.** A tragic opera in which there is no spoken dialogue (*opera seria*). See opera.

**grand relief.** See relief sculpture.

**grant of arms.** See HERALDRY.

**granulated work.** See JEWELRY.

**grapes.** Also called grapevine pattern; in classical art, especially Greek pottery, a decorative pattern in which serrated edged vine leaves and bunches of grapes are arranged on either side of a straight or winding stem line, the leaves usually set opposite each other regularly, the bunches of grapes more often irregularly dispersed. —L.T.S.

**graphic art.** (1) (Newer usage) those expressions of art produced by printing from various kinds of blocks, plates, or type, as etching, drypoint, lithography, wood and linoleum block printing, rotogravure, off-set, letter press, and all other forms of printing (usually *book art* is considered a part of *graphic art,* though sometimes included under *commercial art*); (2) (older usage) all forms of representation, including drawing, painting, and, sometimes, modeling; art forms based upon drawings, painting, or engraving. Whitford and Winslow in *Dictionary of Education.*

**graphic vocabulary.** A term coined by Walter Sargent in 1916 to designate a method of teaching drawing whereby a "vocabulary" of simple forms is acquired by pupils as a basis for graphic expression. Whitford and Winslow in *Dictionary of Education.*

**graphite.** A form of carbon, this mineral probably had little regular use in the arts until crayons or pencils were made of it. Early it was confused with lead, and the ordinary graphite pencil still carries that name. It is dull gray in color and has a greasy texture. Though rather easily abraded, it is entirely permanent and, because of its texture, can be used on soft papers. It is widely distributed as a natural mineral but has also been made artificially since about 1891. —G.L.S.

**graver.** See PRINTS AND PRINT PROCESSES.

**Great Benin art.** See AFRICAN NEGRO ART.

**GREAT BRITAIN, ARCHITECTURE OF.** The English genius, which has expressed itself with such great force in law, in government, and in the written and spoken word, has often seemed to the purist deficient in that plastic sensibility which is the foundation of great architecture. Yet the British people can justly lay claim to a great and ingratiating architectural heritage. Many of its elements were born abroad, but they have been transformed by British conservatism into something so expressive of the English character as to warrant the merit of originality. The same conservatism has avoided extremes either of Mediterranean classicism or Teutonic exuberance; at the same time it has fostered a love of the old buildings which weaves them into the very fabric of English life and history. If traditionalism and reserve have somewhat dampened the ardor which has carried other races to the highest levels of logic, daring, or refinement, compensation may be found in the positive genius of the British people for the landscape art. In no other equal area can one find so many perfect marriages of building to exquisite setting. If the designers have been sometimes lacking in the strictly architectural sense, they have been incomparable masters of the ensemble.

The specific periods in English architectural history are treated fully in the special references; this cursory account may confine itself therefore to an emphasis of major trends. The condition of British architecture prior to and immediately following the Norman conquest of 1066 may be summarized respectively by the tower at Earl's Barton (early 11th cent.), a structure of massive impressiveness, and the cathedral built at Durham between 1096 and 1133. Upon its completion the latter was momentarily the most imposing Romanesque building in the world. Boasting Gothic proportions, it superseded even the enormous monastery at Cluny until it was in turn outmoded by the spread of international Gothic.

The Gothic buildings of England illustrate the transformation to which a movement as powerful as the French Gothic was subjected once it had crossed the Channel. In adopting it the English architects missed entirely the lessons in engineering, planning, and embellishment offered by the Gallic development, but they compensated for this by the perfection of the settings which they provided for their cathedrals. Except at Canterbury (after 1170), they were unable to obtain glazing which in any way rivalled the windows of Chartres or Paris, but in the crossing lantern, esp. the magnificent tower and spire at Salisbury (1220-c. 1258), they designed one of the most impressive motifs in all architecture.

The Gothic period also witnessed the foundation of the great universities at Oxford (13th cent.) and Cambridge (13th cent.), whose ideals and buildings have exerted such a widespread influence upon American academic institutions; the University of Chicago, Yale University, and Duke University are important examples.

The Renaissance, a highly mundane and modern period compared to the Middle Ages, saw an almost complete shift from ecclesiastical to secular building, and the **Tudor** era (16th cent.) is most prominently marked by the appearance of a large number of palaces, such as Hampton Court (1515-40), the Palace of Nonesuch (1537-50), Kirby Hall (1570-1640), Wollaton (1580-1588), Sydenham (16th cent.), and Haddon Hall (1567-1584). The best known designer of the day seems to have been John Thorpe (late 16th cent. and early 17th). At first glance his buildings reveal only a superficial appliqué of the Italian Renaissance motifs which Henry VIII had imported so eagerly, but their plans contain an orderly symmetry which was a more profound derivation from the classic spirit. Several plans are based upon an interesting H or E plan out of respect for Henry VIII or Elizabeth, and a more confident openness is also apparent. It was, indeed, due to the order, prosperity, and highly centralized government promoted by Elizabeth that the medieval fortress gave way to the house with open bay-windows overlooking unprotected lawns and gardens.

England suffered through civil war and revolution during the 17th cent., and her architecture reveals her uncertainty. The closing decades of the century brought in rather unsightly motifs from Germany and the Netherlands. Blenheim Palace, built between 1705 and 1724, betrays the painful persistence of the continental baroque characteristics well into the 18th cent. Nevertheless, in the same century Inigo Jones (1575-1652) imported the graceful Palladian style from Italy, an event

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

of far-reaching significance for both England and America; and Sir Christopher Wren (1632-1723) began his notable career.

Wren left an imposing monument in St. Paul's, London (1668-1710), and he embellished that city with a forest of church spires which testifies to his fecundity of invention; but his broadest conception remained only a plan. It was a layout for the city of London which Wren offered after the great fire of 1666, and which would have brought classic axes and focal points into London's haphazard medieval maze. Property interests thwarted its adoption, but it is possible that L'Enfant borrowed from Wren, as well as from Versailles, the plan for Washington, D. C. in 1792.

By contrast with the 17th cent., the 1700's in England were distinguished by architecture of a most satisfying character. Owing to Palladian influence, prosperity, social and other factors, designs of both exteriors and interiors exhibit a high degree of refinement and finesse which in turn had a pronounced effect upon the bulk of what we think of as colonial architecture of the region from Maine to South Carolina. Though there were fewer noted monumental architects, there arose a series of brilliant and renowned designers of furniture and interiors. Chippendale (1718-1779), Hepplewhite (a. 1786), Sheraton (c. 1751-1806), and the brothers Adam (c. 1728-c. 1792) being the most prominent. In awarding them a high place in the decorative arts, we recognize the English conception that architecture is an harmonious ensemble of furniture, interior, building, and grounds; and the old houses of Salem, Massachusetts, reflect the atmosphere of graceful living which this ideal has fostered.

The foremost position among British architects of the Georgian era rightly belongs to John Wood (1704-1754) and his son, whose designs at Bath, such as Prior Park (1734), Landsdowne Crescent (1794), Royal Crescent (1769), and the Serpentine (1727-54), are only now being fully recognized as landmarks in the history of town planning and as superb examples of the baroque integration of structure and space.

The end of the 18th cent. saw the irresistible rise of the Industrial Revolution, with England playing a prominent part. With it came prophecies of revolutions in economics, society, politics, and architecture, but the ensuing hundred years witnessed a denial of this change. Fearful of the machine in its midst and lacking the ability to create a style of its own, the new century clung desperately to the past through a series of revivals which culminated in outright eclecticism. The productions of this conservatism dominated the outward character of the era; but beneath this veneer the engineers—who make possible any architectural revolution—were laying the groundwork for the 20th cent.

England has the doubtful distinction of being in the vanguard of the revivalists. Neoclassicism became a certainty when Stuart (1713-1788), after a trip to Greece (1751-54), built a Greek temple at Hagley (1758). The remodelling of Kedleston (1761) gave impetus to the movement; and the erection of the Bank of London (1788-1833) gave it genuine authority. Sir John Soane (1753-1837) employed Roman, Greek motifs, and a modern-looking stripped-classic (in the Governor's Court) with freedom and true distinction. Smirke (1780-1867), in the British Museum (1825), employed Greek instead of Roman orders, but the change was merely a substitution. Meanwhile, Romanticism was developing, assisted by important factors. On the one hand romanticism has been a persistent strain in the British character, and during the medieval period it had created the great Gothic edifices which the British so deeply cherish. As early as 1720 Hawksmoor (1661-1736) had obliged All Soul's College at Oxford with a Gothic façade. This was understandable, but even in the 1750's of the Georgian reign Chippendale had to pause to do "Gothick" pieces for several clients, and Walpole built a large residence, the fantastic "Strawberry Hill" (1753-76), in the Gothic "manner," perhaps as a caprice. But serious attention was drawn to the movement when Beckford, a confirmed mediaevalist, employed Wyatt to build his enormous and costly house called "Fonthill Abbey" (1796-1814). When the weak central tower crumbled, Beckford had a ruin on his hands—and was perfectly delighted.

Romanticism scored a triumph when the Houses of Parliament (1838-60) were built, quite naturally, in the perpendicular Gothic around the nucleus of old Westminster Hall. It represented, in one sense, a union of the two competing revivals, for the plan was developed by Barry (1795-1860), a classicist, and the superstructure was designed by Pugin (1812-1812), an erratic but devoted and brilliant mediaevalist. Street's (1824-81) Law Courts (1868-84) paid the same respect to tradition, in this case the nucleus being the Old Temple; and mediaevalism prospered under the hands of Ruskin, Sir George Gilbert Scott, Bently, and others into the 20th cent.,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

when the huge Cathedral at Liverpool was conceived in the Gothic style.

The second half of the 19th cent., however, was dominated by a frantic uncertainty which can only be called eclecticism. The ransacking of all styles of the past was an international disease which England merely shared. Its insincerity is illustrated by the notorious instance of Sir George Gilbert Scott (1811-1878), then an esteemed practitioner. When his Venetian Gothic design for a government administration building failed to please Lord Palmerston, Scott calmly used it for St. Pancras Railroad Station, and satisfied the Prime Minister with something more in the Renaissance "manner." Such were the typical copybook practices of the day.

Meantime, English engineers were quietly leading the world to a new architecture in the last places that the academic architects would have thought beauty could be born, in factories, bridges, and light-houses. These were the true progeny of the Industrial Revolution which England had fostered, and in them materials of the future—metal, glass, and concrete—were first used with logic and daring. As early as 1758 John Smeaton (1724-92) built one of the landmarks of modern architecture, the famous Eddystone Lighthouse near Plymouth. Its binding of cement allowed it to stand where its predecessors had been smashed, perhaps, also, because its lines were "functional" as the word is understood today. Smeaton's triumph pointed the way to Joseph Aspdin's perfection of Portland cement (1824); it was a material incomparably stronger than ancient Roman concrete, and without it a vast portion of modern architecture would be unthinkable.

The workers in metal also kept apace. The first country to boast of an extensive railway system needed new bridges. To this demand Abraham Darby applied metal when he built the first cast iron bridge over the Severn near Coalbrookdale (1775-79), and his success was only the first of many. The Sunderland Bridge (1793-96) covered an unprecedented 263 feet with a single arch. Only five years later (1801) Thomas Telford (1757-1834) submitted a perfectly practicable design for replacing the old London Bridge with a single-arch metal span of 600 feet. And in 1836 Brunel (1826-59) built the Clifton Suspension Bridge near Bristol, covering 702 feet with beautiful ease. These were notable achievements, and served to dramatize the new materials.

Likewise, important advances were made in the expanding factories of England, far beyond the world of "taste." The engineering problem was to free the interior from the tyranny of the masonry tradition: to lighten walls and enlarge windows, to provide through multi-storied structures a beehive of clearly-lighted and unimpeded space-blocks. In one of the most conclusive solutions in architectural history Boulton (1728-1809) and James Watt (1736-1819) solved the problem in a seven-story mill at Salford, Manchester (1801), the forefather of all metal-frame buildings. William Fairbairn's (1789-1874) English Refinery of 1845 improved upon this construction; but mill-designers up to the present day have really only refined upon Watt's stroke of genius.

Factory architecture came into its own in spectacular fashion in 1851 when Sir Joseph Paxton (1803-1865) adopted greenhouse construction on a gigantic scale for the Crystal Palace which housed the International Exposition at London. Its pre-fabricated metal frames encased 1851 running feet—one for each year of the Christian era—and occupied only 1/200th of the floor space. The interior was a procession of space-blocks flooded by a sea of light, protected from the weather by a hovering envelope of glass. This was a new concept of architecture. The world was enthralled and men of vision must have dreamed of unlimited possibilities. Henceforth, no exposition was complete without a similar attraction, and the Galerie des Machines and the Eiffel Tower at the Paris Exposition of 1889 were but breath-taking fulfillments of Paxton's prophecy.

The early achievements of the modern English engineers have, of course, been superseded; they were, nevertheless, great innovations. A further word should be said about a group of designers who, because they worked on a less impressive scale, have received less attention. These men avoided the morass of eclecticism which mired the whole world of academic architecture during the second half of the 19th cent. Outstanding was William Morris (1834-1896), who saw clearly by 1858 that mass-production was filling the world with designless horrors. The industrial displays in the Crystal Palace—rugs, ceramics, textiles, furniture, etc.—were unbelievably bad. Unfortunately, Morris saw the ill as a moral one, and tried to promote through his **Arts and Crafts movement** a return to the medieval work bench. He produced some handsome designs which make the machine products of that day

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

appear hideous, but they were a trickle beside a flood and could only be afforded by the well-to-do. Morris would not compromise with the Machine Age or make his designs available to it; yet his influence was not lost. The famous Red House, which Philip Webb (1831-1915) built for Morris and under his direction at Bexley Heath (1859), is so simple and tasteful as to be styleless and timeless. It was certainly unique in its day, and it is possible that it guided the busiest English architect of the time, R. Norman Shaw (1831-1912) in his well-known London houses. These, though hinting of Renaissance and Queen Anne precedents, possess the orderly simplicity for which Morris pleaded; and we must constantly remember the prevailing gaudiness of eclecticism to appreciate the assurance and restraint of Webb and Shaw.

At the end of the 19th cent. the British Isles produced one of the great pioneers of Modernism, the solitary Scotchman, Charles Rennie Mackintosh (1869-1928). He was a contemporary of Berlage (1856-1934), Otto Wagner (1841-1918), Frank Lloyd Wright (b. 1869), and Peter Behrens (b. 1868), and of their stature. His Art School in Glasgow (1898-99) is a landmark comparable to Berlage's Amsterdam Bourse (1898-1903), and his houses, esp. the one for Dr. Blackie at Helensborough (1902) pointed the way for many subsequent developments.

It was not, however, until the post-war period that Modernism enlisted the energies of a whole generation of young architects in conservative England. The movement was augmented significantly in 1932 when some of the foremost German modernists fled to England; and they were joined by other continentals, like the Russian Lubetkin. Lubetkin's Penguin Pond at the London Zoo (1933) dramatically popularized the movement, and captured the attention of the world. Such masters as Lescaze, Marcel Breuer, Walter Gropius, and Eric Mendelsohn brought with them the most advanced ideas of the continent; and the theories of Le Corbusier (b. 1887) were published (1927) and keenly appraised. Some of the newcomers formed partnerships with the younger men which must have been mutually instructive and beneficial; Mendelsohn and Chermayeff, Lescaze and Henning, Tecton and Lubetkin, Gropius and Fry were firms which commanded wide attention. At that moment in the early 1930's England was the world center of the International Style. But the production was by no means wholly foreign. Progressive young Englishmen began to earn reputations in impressive numbers. In a limited space only a few can be mentioned: Burnett, Tait, and Loring; Anthony Chitty; Wells Coates; Joseph Emberton; Cornell, Ward, and Lucas; L. A. Heaps; Slater and Moberly; Marshall Sisson; E. Owen Williams; Christopher Nicholson; Geoffry Allan Jellicoe; Samuel and Harding; Oliver Hill; and Valentine Harding.

This group is ready and eager to undertake the rebuilding of England after World War II is ended, and they are determined to reassure those who fear that a commission of elderly conservatives will reconstruct England along merely picturesque and half-modern lines. The Industrial Revolution may yet come to its artistic fruition in the country where it started.

—P.C.B.

**Great Serpent Mound.** An effigy mound in southern Ohio, built on a high ridge in the shape of an undulating serpent 1330 ft. long and 2-3½ ft. high. Its function was not burial but probably religious. See Eastern North American Aboriginal art.

**great staff.** See NOTATION.

**Great Wheel.** See INDIAN ART.

**Greco-Buddhist art.** See INDIAN ART.

**Greco-Roman pottery.** See CERAMICS II.

**Greek art.** See HELLENIC ART.

**Greek-Asiatic art.** See EARLY CHRISTIAN ART.

**Greek music, ancient.** With the music of the ancient Greeks the music historian finds the earliest musical system which can be studied in any great detail. Only very little actual music exists which can be identified as coming directly from the ancient Greeks.

Music played a large part in the social life of Greece. The performance of poetry with a musical accompaniment was a highly cultivated art. Music was important in religious rites, in the theater, and was even contested in the Olympic Games.

The Greek musical system grew out of the use of the chief musical instrument, the kithara or lyre, received its definite tuning through the mathematical and experimental discoveries of Pythagoras (582-507 B.C.), and eventually included the seven-tone modal scales which, judging from their geographical names —Dorian, Phrygian, Lydian, Mixolydian— had a much earlier origin than the complete system.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

The Greeks themselves perceived qualities in music which they felt were inherent in the modal scale in which the music was cast. Plato and Aristotle discussed these qualities when they talked of the *ethos* of music. Music in the Dorian mode was conceived to be masterful, suited to military use. The Phrygian was slack, the Lydian soft and effeminate, the Mixolydian mournful and depressing.

For a more detailed discussion of Greek music see Finney, *A History of Music*. For a highly technical discussion and a detailed bibliography see Reese, *Music in the Middle Ages*. —T.M.F.

**Greek pottery.** See CERAMICS II.

**Greek rugs.** Resemble the so-called Smyrna rug. Two kinds—the heavy rugs served for floor coverings in the winter, and the thinner used all the year round. —B.E.J.

**Greek theatre.** See THEATRE.

**green belt.** See CIVIC PLANNING.

**green earth.** Under the names, **terre-verte** and **terra verde**, this was the most usual green pigment of the Middle Ages and the Renaissance. It was known long before that and has been found on wall paintings of classical times. It is a natural earth which owes its color to hydrous iron, magnesium, and aluminum potassium silicates. Shades of it range from grayish green to yellow green. It is very stable and, with thorough grinding, provides a smooth and workable pigment. Its tinting strength, however, is slight. —G.L.S.

**green glass.** See GLASS AND GLASS-MAKING.

**green ware.** Unfired finished ware. See CERAMICS I.

**Gregorian chant.** See MEDIEVAL MUSIC.

**greige goods.** Term designating rayon cloths just off the loom and in unfinished state.

**grey** (or **gray**). Yarns or fabrics in an undyed or unbleached state; also not scoured.

**griffes.** See base.

**grill, grille.** *Arch.* A grating or screen, as of wood or metal, often used in or covering window openings.

**grinding slab.** The stone on which paint is hand-ground goes by this name. Traditionally, the best was of porphyry or granite. In Renaissance painting it was of fair size, being more than a foot across, and the pigment was worked on it with another stone, small and fitted to the hand, known as a **muller**. It was probably developed from prehistoric means of grinding grain and examples of it in different forms are found from the earliest records of the painter's art. In modern practice ground glass has proved to be more convenient than stone. Hand grinding of colors is, however, comparatively rare, having been supplanted by the **color mill**, usually of rotating cylinders and operated by machinery. —G.L.S.

**grisaille** (Fr.). (1) Decorative painting in gray monochrome. (2) A cotton and wool dress fabric with a fancy design. See also ENAMELLING ON METAL.

**grit-stone.** A course or fine-grained sandstone of various degrees of hardness. It is composed of small grains of sand united by a cementing material of an argillaceous, calcareous, or siliceous nature. —J.M.M.

**grog.** Clay that has been burned and crushed. 30 to 40 parts grog (10 to 50 mesh) to 70 to 60 parts clay may be used in ceramic sculpture.

**groin.** The projecting solid angle formed by the meeting of two vaults, growing more obtuse at the top.

**Grolier.** *Book.* Ornament following the style used by Grolier in the 16th cent.

**gros bleu.** See CERAMICS II.

**grosgrain.** Firm, stiff, closely woven, corded fabric. Ribs vary from 50 to 70 per inch. Filling may be of cotton but usually silk or rayon.

**grosse verdure.** See TAPESTRY.

**grotesque.** As a decorative element means an ornament, painted or sculptured, which consists of fantastically shaped human beings, animals and fabulous beings, joined together by garlands, wreaths of flowers, fantastic architectural elements and other ornaments like arabesques (q.v.) and scroll-work (q.v.). The word comes from the Italian *grottesco*, an adjective formed from *grotta*, for in the excavated ancient Greek and Roman palaces this type of decoration has been especially found. These antique decorations became known after 1490 from which time on they were widely used in Italian decoration. But it was Raffael and his collaborators who really mark the starting point for the revival of this decora-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

tive element in modern times. It has to be stressed that the grotesque did not develop in contrast with the arabesque but in close connection with it (cf. Giovanni Paolo Lomazzo, *Rime*. Milan, 1587). The usage of grotesques became favorite with painters and sculptors as well as with ornament engravers. The development, enrichment, variations, and spreading of this ornament were up to the individual artists who had no rule to follow except the symmetrical built up of grotesque design. From Italy, the grotesque went to Northern countries, too (esp. by means of ornament engravings), and the Netherlands were very industrious in developing an original form in mixing grotesque elements with their typical scrollwork. See Alois Riegl, *Stilfragen,* Berlin, 1893; Jacob Burckhardt, *The Civilization of the Renaissance in Italy,* Esslingen, 1912; English trans., London, 1937; Robert Hedicke, *Cornelis Floris und die Florisdekoration,* Berlin, 1913; Peter Jessen, *Der Ornamentstich,* Berlin, 1920; Rudolf Berliner, *Ornamentale Vorlageblätter,* Leipzig, 1926 and *Katalog der Berliner Ornamentstich-Sammlung,* Berlin, 1935; Fiske Kimball, "Sources and Evolution of the Arabesques of Berain," in *The Art Bulletin,* vol. XXII, No. 4, 1941. —L.P-E.

**grottesque.** See arabesque.

**grotto.** See folly.

**ground.** (1) The ground of a painting is the preparation laid over the support, providing a smooth, even-textured, and even-toned surface for the design proper. The most widely applied of such grounds for many centuries was a mixture of either gypsum or chalk with glue, a substance known as gesso, put over the wooden panels that were painting supports during the Middle Ages and the Renaissance in Europe. Later, oil grounds containing similar inert materials, probably with a frequent addition of white lead, were used on canvas supports. Prepared commercially, these are still common. (2) *Etch.* An acid-resistant coating on a plate. —G.L.S.

**ground, aquatint.** *Etch.* Finely powdered asphaltum or resin, used in making aquatints.

**ground bass** (It. *basso ostinato*). A short theme repeated over again in the bass with varied melodic and harmonic accompaniments.

**ground, etching.** Hard ground used for line etching, composed of asphaltum, beeswax and other ingredients.

**ground harp.** See MUSICAL INSTRUMENTS.

**ground line.** See PERSPECTIVE.

**ground, liquid.** Hard ground dissolved in chloroform, used in making line etchings.

**ground plane.** See PERSPECTIVE.

**ground psaltery.** See MUSICAL INSTRUMENTS.

**ground, soft.** Same as hard ground (see ground, hard) but with 50 per cent tallow added, used in making soft ground aquatints.

**grout.** A mixture of cement or lime and sand or gravel, poured when semiliquid between stones or bricks in a structure, as a wall.

**guardant.** See HERALDRY.

**guard bands, of a rug.** The border and field of a rug are generally flanked with narrow strips called guard bands.

**Guidonian hand.** See solmization.

**Guidonian notation.** See NOTATION.

**guilloche.** (1) *Book.* A design composed of two or more bands intertwining and a continuous series. (2) *Arch.* In ancient eastern and classical art, an ornamental pattern composed of two or more curved lines or bands intersecting and interlacing, leaving circular centres or eyes, sometimes filled with rosettes.

**guitar.** See MUSICAL INSTRUMENTS.

**gules.** *Her.* Red.

**gum elemi.** See elemi.

**gunbad.** A monumental tomb. See ISLAMIC ART.

**Gupta art.** See INDIAN ART.

**guri** (Jap.). A lacquer technique. Successive layers of various colored lacquers carved V-shape to show the striated colors as a pattern. —J.A.M.

**Gustavian style.** See SCANDINAVIAN ART.

**guttae** (pl.). A series of droplike ornaments, as on the lower face of a mutule in a Doric entablature.

**gutter.** A channel or trough, generally along the eaves of a structure, to carry off rainwater.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**gymel.** (L. *gemellum*). Twin song. A form of organum or part-singing in 3rds, used in England in the early Middle Ages.

**Gymnopaedia.** An exhibition and festival held in honor of Apollo, Artemis, and Leto from about the 6th to the 10th of July at Sparta; included awards for accomplishments of boys, youths and men in dancing, gymnastics and music. Old bachelors were excluded.

**gypsum.** Best known now as **plaster of Paris**, some form of gypsum has been used for a substance to be molded or carved since ancient times. Pulverized, it has served as the common inert material of grounds, the gesso in panel paintings. As a natural deposit, a calcium sulphate dihydrate, gypsum is found widely over the earth's surface, though it occurs in many varieties. Most of that used in the arts is burned and, when it is again combined with water, sets rapidly to a firm plaster. It is the most common of casting materials. It is generally stable but is slightly soluble in water and is fairly soluble in dilute hydrochloric acid. —G.L.S.

**gyron.** See HERALDRY.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

# H

**Haarlem school.** A school of art centering in Haarlem whose chief characteristic was truthfully depicted garden backgrounds first introduced by Dierick Bouts. This school was a forerunner of painting-schools that were to flourish in Holland in the 17th cent. —R.L.W.

**habaki** (Jap.). A metal stop fitting both sides of a Japanese sword-blade to keep the edge of the blade from coming in contact with the hilt. —J.A.M.

**Haban ceramics.** See CZECHOSLOVAKIA, ART OF.

**habanera.** A dance in 2/4 time popular in Havana; frequently syncopated and performed in a slow, voluptuous manner.

**Habbé art.** See AFRICAN NEGRO ART.

**haboki** (Jap.). A feather brush used to dust up the ashes of the fire brazier in connection with *cha-no-yu* (q.v.).

**hematite.** Although there is some literary reference to the use of this mineral, a hard, natural variety of anhydrous ferric oxide, as a pigment, probably its chief utility in the arts has been to supply a stone suitable for making burnishers for gold leaf. —G.L.S.

**Haggadah.** The report of the exodus of the Jews from Egypt, as told on the Passover Evening in the Jewish family. More frequently than any other Jewish text the Haggadah was written and illustrated during the Middle Ages and the Renaissance. See JEWISH ART. —H.G.

**hagiopolitan.** See eastern chants.

**Hagi yaki** (Jap.). Pottery made in Nagato province.

**hagoromo.** See SYMBOLISM IN FAR EASTERN ART.

**Haida art.** See Northwest Coast Indian art.

**hainsa** (Skr.). The emblem of *Mon* Sovereignty, often seen in Siam adorning temple flag poles.

**haircloth.** A cloth combining cotton or linen warp with a weft of horse-hair.

**haisaji** (Jap.). A metal spoon for shaping the ashes around the charcoal fire. A utensil used in *cha-no-yu* (q.v.).

**hakemei** (Jap.). Lacquer technique in which brush marks are deliberately shown as a style of decoration.

**hakudo** (Jap.). "White bronze," composed of copper and nickel.

**Hakuohô art.** See JAPANESE ART.

**half-binding.** *Book.* A book with leather corners and leather back coming well over the side of the book is said to be half-bound. In three-quarter binding, the back leather covers more of the side, and the corners (q.v.) are larger. The term is obviously short for half-leather binding. The term is also used for any binding in which the covering of the spine and corners is different from the material covering the sides. Also used for the material itself. —H.E.S.

**half circles.** In Greek art, esp. pottery, half circles are used concentrically to make an ornamental pattern.

**half distance point, half measuring point, half point of distance, half station point.** See PERSPECTIVE.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**half relief.** See relief; relief sculpture.

**half-timbered.** *Arch.* Built of a timber frame, the spaces in between being filled in with masonry or with plastered laths.

**Hallenkirche.** See GERMAN ART.

**Hallstatt art.** See AUSTRIAN ART; PREHISTORIC ART.

**Halmstadgruppen.** See SCANDINAVIAN ART.

**halo.** Seen in oriental art as a nimbus (q.v.) back of the head and sometimes completely surrounding the figure. Said to be derived from the fact that the ancients were believed to have been able to see an aura emanating from the body of a holy person. —J.A.M.

**halveflossa.** A Swedish technique which consists of a flat texture forming the background and the knots or tufts woven in to form the design. Both the loop knot and the cut knot are used. —B.E.J.

**hammer dressing.** In masonry: Roughest description of dressing or tooling after scabbling.

**Hammond organ.** See MUSICAL INSTRUMENTS; electrical instruments.

**han** (Ch.). Flat jade ritual ornament in the shape of a cicada; placed on the tongue at time of burial.

**Han art.** See CHINESE ARTS.

**hand.** The texture or feel of a fabric, esp. of silk.

**handcraft.** Productive creative work done by hand, with the aid of simple tools and machines. (Note the new spelling, *handcraft,* now coming into general use by art educators and regarded as an improvement over *handicraft.*) Whitford and Winslow in *Dictionary of Education.*

**hand tufted carpet.** See carpet structures.

**Han dynasty porcelain.** See CERAMICS II.

**haniwa** (Jap.). Unique hollow pottery post-like forms representing human beings, animals and houses, which were apparently implanted around the exterior of ancient tumuli in Japan. Literary tradition explains them as humane substitutes for interment, alive, of wives, retainers, etc., in the tomb of the deceased. See JAPANESE ART. —J.A.M.

**hardening on.** *Cer.* Low firing of underglaze decoration to remove oils before glazing. See CERAMICS I.

**hare's fur glaze.** Radiating glaze sometimes seen on Chinese pottery of the Sung dynasty, especially on Temmoku ware (q.v.).

**harmika.** See stupa; INDIAN ART.

**harmonic.** *Mus.* (1) An upper partial (see ACOUSTICS), frequently used in the pl.

**harmonics.** (2) Relating to harmony.

**harmonica.** See MUSICAL INSTRUMENTS.

**harmonic analysis.** The analysis and measurement of the cross section of the structure of a tone in terms of the number of partials present, their distribution, the relative amount of energy in each, and their phase relationships.

This type of analysis has long been known in mathematics and physics but has not come into general use in music and psychology on account of the complicated nature of the measurement and, therefore, the general ignorance prevailing on the subject. Now, however, we have instruments which give us measures of precision and are great time-savers so that we can say that timbre is very satisfactorily harnessed for experimental work in the laboratory, and we can collect samples of sound waves in any form of music and submit them to exact measurement. The term harmonic analysis as here used with reference to the analysis of the cross section of a tone should be distinguished from the term harmonic analysis as it prevails in the treatment of musical harmony. In radio and in the recording of music, utilization of knowledge of the harmonic structure of sound plays a very important role.

There are three fundamental steps in the measurement: (1) the taking of an **oscillogram,** which is a large and detailed picture of the form of the sound wave; (2) the running of this wave form through an harmonic analyzer; and (3) the representation of the readings from the analyzer in a diagram called the **tone spectrum** (q.v.). The analyzer works like a very complicated calculating machine and delivers the results of the analysis of the wave form in terms of figures on dials, which show (a) which partials are present within a range of 40 or more, and (b) what per cent of energy of the whole tone comes from each of the partials. In physics we speak of the component elements of a rich tone as **partials,**

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

calling the fundamental tone the first partial; whereas, in psychology and music, we speak of **overtones**, calling the second partial the first overtone and the first partial the fundamental. —C.E.S.

**harmonic interval.** See interval.

**harmonic inversion.** See inversion.

**harmonic minor scale.** See scales and modes.

**harmonium.** See MUSICAL INSTRUMENTS.

**harmonization in Jewish music.** See JEWISH MUSIC.

**harmony.** (1) The representation of all opposed elements in a work of art in such a way as to become a pleasing unity. Since quite generally the task of art is to bring the distinct parts into a unified whole, or to demonstrate them as components of one unified law and thus to excite aesthetic satisfaction, harmony is the main requirement of every art.

But we must discriminate between this more general meaning and its more limited sense. The latter has been restricted to Greek art and to all art which is related to it, such as Hellenistic and Roman art, the Renaissance and classicism. The harmonic effect is realized in classic works of art because the different parts which are represented have become the parts of one idea or of an ideal whole. The resulting effect is that the whole may be seen immediately and easily, that the highest possible equilibrium is achieved, and that all lines are continuant and tending to return to their starting point. Only by showing these elements unmistakably clearly can there be harmony in the Greek and classic sense.

In order to achieve this harmonic pleasure certain rules and measures were set down in the so-called canons from the very beginning. On the basis of these canons the measurements and proportions of the human body were exactly fixed. One of the most famous and well known systems of proportion, of dividing the whole into pleasant parts, is the *Linea Aurea.* —A.J.S.

(2) *Mus.* Simultaneous sounding of several different tones; chord; system of relationships between chords to be applied in order to make successions of chords aesthetically meaningful in terms of the idiom chosen for the composition under consideration (see chord; idiom). Educationally: the discipline setting forth the principles of harmony. —E.K.

**harp.** See MUSICAL INSTRUMENTS.

**harpsichord** (Fr. *clavecin,* It. *arpsichordo, clavicembalo*). The precursor of the pianoforte. The strings were plucked by means of quills attached to "jacks". See MUSICAL INSTRUMENTS; mechanical instruments.

**hashira-e** (Jap.). *hashira,* pillar; *e,* painting; thus a pillar painting or a narrow panel to hang on a pillar. Generally applied to a long narrow form of Japanese print, ca. 28 in. x 5 in. —J.A.M.

**hatchway, hatch.** An opening in a deck, floor, or roof of a structure affording passage from one level to another.

**haunch.** Either of the parts of an arch at the sides of the crown between the crown and the springings.

**Haviland china.** See CERAMICS II.

**hawksbeak.** A Greek compound moulding based on a cavetto of which the fascia has become an ovolo or a cyma reversa and the concave curve has been undercut and may or may not terminate in a short reverse curve at the bottom; when ornamented carries a Doric leaf pattern. —L.T.S.

**hawthorn design.** A pattern often seen on Chinese blue and white porcelain which is miscalled for the plum pattern.

**head.** (1) *Book.* The top of the book is described as the head. But a headpiece is the ornament (in printing) at the top of the page commencing a chapter. (2) *Arch.* The lintel of an opening.

**headband.** *Book.* The silk or other band at the top and bottom of the back of a book. They are of two kinds, the one worked or made, the other simply stuck on, as it were. The former, besides being ornamental, is useful, but the latter is ornamental only. —H.E.S.

**headdress.** See COSTUME ART.

**header.** See **bond-stone.**

**headers.** In masonry: The name applied to stones, the lengths of which are 2/3 to 3/4 the thickness of the wall, laid transversely.

**heading.** In masonry: The vertical side of a stone perpendicular to the face.

**heading joint.** In masonry: The stratum of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

mortar between the vertical surfaces of two adjacent stones.

**hearth.** *Arch.* The floor of a fireplace.

**heat absorbing glass.** See GLASS AND GLASS-MAKING.

**heaume.** Ancient spelling of helmet. See HERALDRY.

**heavy ink technique.** See CHINESE ARTS.

**Hebrew theatre.** See THEATRE.

**heckelphon.** See MUSICAL INSTRUMENTS.

**Heian art.** See JAPANESE ART.

**heidatsu** (Jap.). A style of decoration which makes use of thin sheet metal, especially gold or silver, cut into perforated patterns (which may also be engraved) and laid into lacquered surfaces. As the lacquer hardened the decoration became part of the surface itself. —J.A.M.

**heien** (Jap.). A term indicating "level distance" in a painting; mountains depicted as seen across water.

**height line.** See PERSPECTIVE.

**Heimatkunst.** See Biedermeier.

**Helladic architecture.** See AEGEAN ARCHITECTURE.

**HELLENIC ART** developed in the Greek peninsula, on the islands of the Aegean, and on the shores of Asia Minor in the first millennium B.C. Greek colonists carried it to Southern Italy, Sicily, North Africa, Southern France and Spain as well as to the Balkans and the Crimea. In the 3rd and 4th cent. B.C. Alexander the Great and his successors extended the influence of Greek art to Syria, Egypt, Mesopotamia, Iran, and India. Hellenic art supplied the foundations for Roman and Byzantine art; as a normative expression of the humanistic idea it has remained a living force in the later development of European and American culture.

The history of Hellenic art may be divided into six major phases: Proto-Geometric, 1100-900 B.C.; Geometric, 900-700 B.C.; Orientalizing, 700-600 B.C.; Archaic, 600-500 B.C.; Classical, 500-300 B.C.; and Hellenistic, 300-100 B.C. The transition from Greek to Roman art occurs in the 1st cent. B.C. and 1st cent. A.D.

The origin of Hellenic art has long been a subject of controversy. When Mycenaean art was discovered, many scholars tended to emphasize the importance of Mycenaean elements for the formative stage of Hellenic art. Others regarded the Dorian invasion (ca. 1100) as a decisive event and the Dorians as the originators of the new Geometric art. Others yet observed that many Geometric styles developed in the Mediterranean area during the period of migrations (13th—9th cent. B.C.) and regarded the Greek Geometric style as one special type of this general Mediterranean style of the period.

Although the excavations in Athens (Kübler and Kraiker, *Kerameikos,* 1939; O. Broneer, *Hesperia,* 8, 1939, 416) illustrate the transition from late Mycenaean to the earliest Hellenic style, the birth of Greek art remains miraculous. Athens was never occupied by the Dorians; the Dorian invasion cannot, therefore, be directly responsible. Yet the change from the debased, de-naturalized late Mycenaean style to the crystalline system of the Proto-Geometric signifies a change of fundamental principles. Despite the modest character of the Proto-Geometric vases and the simplicity of decorative elements the Proto-Geometric style already partakes of that lucid logic that is a fundamental trait of Hellenic art. In contrast to the dynamic movement of the Minoan and Mycenaean ornament, the new style is dominated by tectonic order, by rhythmic spacing of decoratice elements, by close relation between the structural form of the vase and the horizontal zones of ornament.

*Geometric.* "Geometric" elements of decoration such as circles, parallel lines, triangles, meanders, and hour glasses are found in many arts. What distinguishes the Greek "Geometric" style is the completely abstract, mathematical character of the underlying compositional system and the perfection of draftsmanship characterized by the "tyranny of compass and ruler" (Payne). The Greek artists knew at all times how to concentrate upon a few clearly limited problems which they pursued with single-minded devotion until all possibilities of the approach were exhausted. They were really the first to recognize artistic problems and to conceive of art as a rational activity. Yet Greek art expresses the concept that art reflects an objective pre-established order of the universe. The Geometric period symbolizes this order by a static geometric system of abstract forms; the Orientalizing, by its sequences

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

of monsters, animals, and plants; the Archaic through automatic angular movement expressed by human beings; the Classical through the organic flow of movement again expressed through human beings; and the Hellenistic through a vast variety of naturalistic rhythmic motions that pervade the entire realm of nature. Two-dimensional geometry is the most striking manifestation of early Hellenic art, but no less important is the feeling for three-dimensional structure displayed in the shapes of the Geometric vases. Dominating the entire Greek art is the absolute conviction that three-dimensional structure is the true essence of all things. In spite of their scientific inquiries into the nature of optics and their great knowledge of the phenomena of color and light, the Greeks never completely entrusted themselves to the optic vision. This remained the prerogative of the modern cycle of art (15th to 19th cent. W.M. Ivins, *On the Rationalization of Sight,* 1938).

Painted pottery is the leading art of the Geometric period. The shape of the vase and its painted surface are in complete harmony. The decorators seek to visualize the structure of the vase. As the vase is built up of added rings so is the ornament built up in uniform, horizontal zones. The two-handled jars (*amphorae*) and the huge mixing bowls (craters) were placed on tombs or in sacret precincts. In Athens ("Dipylon" vases), Corinth, Thera, and the Peloponnesus the vases are decorated with circles, parallel lines, triangles, and meanders drawn with wiry precision. In the Eastern islands, in Crete, and in Asia Minor connected circles, spirals, parallel lines prevail; the composition is looser, the draftsmanship broader. Animals and men are represented in the developed Geometric style. At first they are displayed in uniform rows that convey no definite meaning. Later, they are organized in simple compositions with recognizable types of subject matter such as battles on land and sea, chariot races, dances, and the solemn lament for the dead. The figures, mere black silhouettes, are composed of geometric forms and serve as a symbolic shorthand transcribing but not reflecting reality. In size and arrangement they are treated exactly like the geometric ornaments and do not break the rigid compositional divisions.

Geometric sculpture features small bronzes and terra cottas of birds, horses, and bulls (Delphi, Olympia) which are quite similar to the bronze figurines of the Early Eurasian Iron Age (Hallstatt). The few human figurines, which include some groups (dance, Olympia), are loosely constructed and tentative, and only the best of the animal groups approach the tectonic clarity of vase decoration (mare and foal, Olympia; fawn, Boston; stag and dogs, Olympia). Cf. V. Mueller, *Antike Plastik in Grienchenland,* 1929, W. Lamb, *Greek Bronzes,* 1929.

The architecture of the Geometric Age is as yet imperfectly known. House foundations show rather irregular plans (Crete, Eleusis, Thermos, Olympia, Samos). Temples are either long narrow halls or short, almost square rooms (*Dreros*). The central column or the central row of supports inside seems a survival from Minoan architecture. Terra cotta models of buildings from Argos and Perachora have columns placed in front of a small rectangular cella and a (prostyle) high pitched roof. (Payne, *Perachora,* 1940). Some knowledge of stone building survived from Mycenaean times but unbaked brick and wood are the important materials. Altogether these Geometric buildings must be visualized as rustic sheds and huts, perhaps decorated with painting or woodwork; they do not show the definite stylistic system of vase painting.

*Orientalizing.* The Greek feudal system underwent a transformation toward an urban, commercial culture. The adoption of the Phoenician alphabet led to literacy. The cosmogony, the science, and the law codes of the Near East began to exercise considerable influence upon Greek thought. Hesiod interpreted the universe in terms of Oriental hierarchies of gods and monsters. He opposed the feudal ideal of noble birth, physical strength and undaunted courage with a glorification of justice and equality as the divine foundations of human society. The lyrics of Alcman portray a rich new world in which real events enter the realm of mythological fancy. And as Greek mythology achieved a more grandiose and universal quality through the influence of Oriental cosmology, Greek art also gained a sense of powerful grandeur, when it was brought in contact with the colossal creations of the Near East and later of Egypt. The symbolic transcription of mythological reality was discarded in favor of representation. Vase-painting displays in large panels or friezes pictures of full-blooded monsters, animals, and occasionally mythological subjects (Cretan, Proto-Corinthian, Proto-Attic, Melian). The subordination of surface decoration to the structure of the vase is relaxed. The ornamental vocabulary changes

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

from static geometric motifs to highly stylized, floral arabesques. The figures, though still two-dimensional and conceptual, show a physical reality which is expressed by bulky forms, ornamentalized details, and symbolic polychromy. The luxurious splendor of painting is restrained and systemized by the end of the period, in the miniaturistic battles and friezes of the Chigi Vase (Proto-Corinthian) or in the grand, sculpturesque chariot and lion of the Pyraeus Amphora (Proto-Attic). And the first examples of large-scale painting appear (metopes Thermos).

Sculpture was eminently suited to express the massive physical power that appeared to the artists as the fundamental feature of "reality". This explains the rise of monumental sculpture in stone. Draped figures, standing and seated (Prinia; Auxerre-Louvre; "Hera", Samos; Nikandre, Delos) are fashioned after Near Eastern types and the nude walking youths follow Egyptian models. The earliest reliefs depict the same rows of riders, monsters, and animals as the Orientalizing vases (Prinia, Vrocastro). In the marble youths from Attica (Dipylon head; Met. Mus., N. Y.; Sunion) there is a synthesis of Geometric order and Orientalizing mass. They represent a generalized human ideal, as opposed to the specific religious social concepts expressed by the sculpture of the Near East and Egypt. They surpass their Egyptian prototypes in tension of forms and energy of movement; and their Oriental models in systematic organization and correlation of forms. This formative, "Daedalic" style, is represented, with local variations, throughout Greece by large stone-images and small bronzes, ivories, and terra cottas. Cf. H. Payne, *Necrocorinthia,* 1932, R. Jenkins, *Daedalica,* 1936, P. Knoblauch, *Studien,* 1936, F. R. Grace, *AJA* 46, 1942, 341 ff.

The development of the Doric and the Ionic orders in architecture parallels the development of definite types in sculpture. The temples gain in substance and volume, and their proportions widen. There is an initial use of stone rather than wood, although a combination of wooden structure and terra cotta revetment remains popular far into the archaic period. During the early phase the buildings were probably burdened with floral and figurative motifs. Traces of this experimentation appear in the door-sills of the temple in Prinia, and in the discarded decorations from Thermos and Calydon. The brief use of the luxurious Aeolic palm-capitals derived from Syria (Megiddo) indicates the same tendency (Neandria). Order and restraint predominate by the end of 7th cent. The Doric order has developed its essential features (Tiryns; Heraeum, Olympia; Heraeum, Argos); the Ionic is soon to follow. A number of temples without porches, (Prinia; Gortyn; Demeter, Selinus) particularly in Crete, represent perhaps an older type.

*Archaic.* In contrast to the experimental and revolutionary character of the Orientalizing period, the archaic period (6th cent. B.C.) is a time of steady progress toward humanization and refinement. As the solemn grandeur of Solon's poetry is followed by the joyous refinement of Anacreon's so is the massive strength of early archaic sculpture replaced by a courtly refinement in the **Peisistratid era.** Archaic painting and sculpture is unsurpassed in beauty of the individual form, feeling for material and in its flawless craftsmanship. Sculpture emerges as the leading form of artistic expression in Greek culture. In the numerous statutes of youths and maidens (esp. Acropolis, Athens; Argos; Delphi; Corinth (Tenea); Samos; Miletus) and in the architectural sculpture of friezes, metopes, and pediments (Korfu; Acropolis, Athens; Assus; Selinus; treasuries of the Syracusans, Siphnians, and Athenians in Delphi, of Megarrans in Olympia; of Artemisium, Ephesus) the parts of the human figure are transformed from a linear ornamentalism to a sculptural stylization. The growing superficial naturalism of details does not change the basic structure of the figures which is still abstract. The generalized expression of austerity prevalent in the early archaic period is differentiated into a number of typical expressions dictated by the conventions of an aristocratic ideal; they range from exaggerated friendliness (goddess, Berlin), lusty good nature (calf bearer, Athens), modest confidence (head Rayet, Copenhagen), to courtly politeness (many Korai, Acropolis; pedimental group from Eretria). The interest in physical beauty far outweighs any concern for emotion or intellect.

Archaic vase-painting is an illustrative art always conscious of its decorative function. Nearly all Greek mythology is represented, and gradually scenes of sports, dances, concerts, dinners, and even of business and trade rival the earlier subject matter. At first the painters tell their stories with epic uniformity; then, attending the birth of Greek drama, dramatic concentration becomes an important concern. Schools of vase painting

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

flourish in Sparta, Corinth, Chalcis, and Ionia ("Caeretan" hydriae), but ultimately a brilliant series of draftsmen headed by Exekias wins the artistic leadership for the black-figure style of Athens (J.D. Beazley, *Attic Black-Figure,* 1929). The Attic red-figure technique (530 B.C.) alters that character of vase-decoration by introducing foreshortening which gives to the figures a space of their own. Clear compositions, beauty and economy of lines, and ornamentalization of details place the red-figure painters Epictetus, Euphronios, and Euthymides among the greatest outline draftsmen of all times.

Archaic architecture amplifies and elaborates the types created in the Orientalizing period. The heavy proportions of early archaic are gradually lightened; capitals and profiles are made more elastic and tense. The different kinds of ornament are brought into definite relation with the structural system. Color, which dominated the buildings with terra cotta revetments, is used to enliven the ornament in stone and marble buildings and to emphasize parts that are structurally important. The coherence of archaic temples reflects the growth of systematic rational inquiry into relations and proportions. Definite mathematical ratios as well as technical advice on problems of construction were probably included in the publications of the designs. The typical plan of the Greek temple now features an entrance porch (***pronaos***), the main chamber containing the image (***cella, naos***), and often a room in the rear (***opisthodomos***). This structure was surrounded by a colonnade (***peristasis***). A sloping roof covers the entire building. The cella is sometimes divided into nave and aisles by two inner colonnades. Notable Doric examples were found in Corfu, Thermos, Selinus ("C"), Sele (Hera), Paestum ("Basilica", "Ceres"), Athens (Old Athena), Cyrene (Apollo), Corinth (Apollo), Sunium, Assus, and Delphi. Huge Ionic temples were erected in Ephesus by Chersiphron and Metagenes and in Samos by Rhoicus; they include a double colonnade (***dipteros***). The subordination of ornament and sculptural adornment to the tectonic elements and the exacting finish of every part bestow a peculiar purity and strength upon these temples.

*Classical.* The foundations of the entire Greek culture undergo a change in the transition from the archaic to the Classical period. Human reason is regarded capable of finding *a priori* the nature of reality. Man and the universe are conceived in a divine order ruled by rational and lawful deities. Characterized by free will and rationality, the new human ideal is projected into the forms of traditional mythology where the gods and mythical heroes typify human attitudes in normal and ethical problems. The conflict of the tragic hero with the divine order is a problem of universal validity. The political recognition of the belief in man is reflected by the rise of democracy. The power of self-analysis is shown by the description of the war with Persia as a conflict of two different ways of life. Rational idealization thus constitutes the basis of Classical thought.

Greek drama and sculpture lead the way, while in philosophy, science, and painting the change is more gradual. Of the two leading arts drama develops a greater emotional insight, but sculpture makes an epochal advance in structure that remained unrivaled until the advent of modern abstract art. In archaic art the composition of statues was based on semi-abstract rhythms. The advance toward verisimilitude was limited to external appearances . In Classical art, the statue expresses an equilibrium of organic motions affecting every part of the body. Dynamic interrelation replaces static correlation. The relation of the statue to space undergoes a similar change. The archaic statue is like a rectangular pillar, and all the major forms are developed within the four planes. Although the four planes are still ideally retained in the classical statue and the mass of the body is roughly parallel to the frontal plane, the lower part and the head and shoulder are turned in rounded movements. The expression of unified movement has replaced the accentuation of the four different views.

The Classical period is the age of great artistic personalities. Unfortunately, the style of the greatest artists—Phidias, Polycleitus, Myron in the 5th cent., Scopas, Timotheos, Praxiteles, Bryaxis, and Lysippus—in the fourth—must be recognized from fragments, reflections, and Roman copies, while other masters, equally famous, remain phantoms. The marble statue of a boy by Critios, the magnificent Victory of Paeonius, possibly the Hermes of Praxiteles (doubtful, cf. *AJA* 1931) are among the few Classical sculptures whose authors are known. We owe our knowledge of Classical standards to anonymous but great originals; the bronze statue of bearded god from Cape Artemisium, easily the grandest of all Early Classical sculptures; the austere charioteer from Delphi; the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

poetic relief of the Ludovisi Throne; and for the later Classical sculpture the bronze boy from Marathon, the Demeter from Cnidus, the pensive head of Aphrodite (Boston), and a vigorous and brutal portrait of a boxer from Olympia. Yet we could not have traced the development of Classical art, had the architectural sculpture been lost. Aegina (480), Olympia (460), Parthenon, Athens (448-432), Hephaestium, Athens (440), Erechtheum, Athens (420-405), Nike Balustrade, Athens (405), the Nereid Monument, Xanthus (ca.400) and a number of unattached pedimental sculptures and acroteria (Niobids, Rome and Copenhagen) reveal to us the harmony of lofty spirit. The sculptures from Tegea (380), Epidaurus (360), and the Mausoleum of Halicarnassus display the increased laxity of form and complexity of movement that distinguish later Classical art. Numerous votive and sepulchral reliefs round out the picture.

Classical art is often praised for its naturalism or, conversely, for its idealism. Classical sculpture, although humanized, represents a general type. The statues are expressions of the universal order in human form; they are a perfect harmony of physical beauty, cosmic validity, and ethical greatness. Formally as well as psychologically, they express not the accidental appearance but the underlying principles of the organic universe moved by eternal laws. The High Classic age of Phidias insists upon the enduring states of existence; the Later Classic explores the contrasts of restful contemplation and emotional action.

Classical architecture is infused with a sense of organic growth and equilibrium; but its proportions are perfected by mathematical or geometric formulae. For the Doric order, the temple of Zeus in Olympia, built by Libon (456) is the first great Classical building. A complex of fine classic temples is concontrated on the Acropolis of Athens reconstructed under the leadership of Pericles (450-430). As their entrance, Mnesicles designed a festive two-winged gate, the Propylaea (437-432). Crowning the Acropolis is the most perfect Doric temple in the world, the Parthenon, built by Ictinus and decorated with sculpture after designs by Phidias; a work in which the smallest form vibrates with musical life. Compared to their archaic predecessors the Ionic temples of Athena Nike (425 ?) and Athena and Erechtheus are small, almost fragile expressions of a poetic grace which is enhanced by their pure, rhythmic ornaments. Ictinus also designed the Mystery Hall (Telesterion) in Eleusis and a temple of unusual plan in Phigalia, while another great but anonymous architect designed the Hephaestium in Athens and a temple in Sunium (W.B. Dinsmoor, *Hesperia* suppl. T, 1941). The Doric and Ionic orders had symbolized organic life through abstract and semi-abstract forms. Later Classical architects portray organic growth more literally by means of the acanthus ornament and other forms adopted from actual plants. The popular Corinthian order (Choregic monument of Lysicrates, 334 B.C.) in which the capital consists of vegetable forms, is the last order of Classical architecture. The architects use its rich, natural forms in the interior (Athena, Tegea, by Scopas; Tholos, Epidaurus, by the Younger Polycleitus) reserving the traditional Doric for the façade. The Early Classical temples are unified by a consistent use of the Doric order. These later temples, however, separate the luxurious complex life of the interior structure from the restrained appearance of the exterior, a principle which applies equally to much fourth century sculpture. The end of Classical architecture coincides with the **Ionic Renaissance** championed by the architect Pytheos (Maussoleum of Halicarnassus, 350 and Temple of Athena, Priene, 334); he abandons the pursuit of complex refinement and aims to make his structures dominate their surroundings through colossal scale, largeness of detail, and accentuation of height.

The Early Classical period boasts a galaxy of draftsmen. Without the vase-paintings by Kleophrades Painter (Epictetus), by the "Berlin Painter", the "Pan Painter" by the "Pistoexenos Painter", by Brygos and Douris we could never appreciate the varied aspects of this period. Their complicated compositions and isolated figures of solitary grandeur rival the pediments of Olympia. The subjects range from the loftiest myth to the aftermath of a drinking bout. The best vase painters parallel and follow the lead of sculpture; others seek to emulate the advance of painting ("Niobid Painter") and are confronted with a dilemma: either deny the tectonic character of the vase altogether, introduce color, and make miniature painting on vases, or retain the red-figure technique, the decorative arrangement, and make imperfect imitations. The problem was never solved. The best High Classical draftsmen reject ambitious subject matter to draw quiet groups

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

of two and three figures on vases with white ground, filling the outlines with a few flat colors (Achilles Painter). Thereafter vase-painting drifts into mediocrity.

Classical painting explores for the first time in Greek history problems connected with the optic illusion: foreshortening, perspective, local color, and light. Polygnotus (ca.480-440), "the painter of ethos", is extolled by literary sources as an exponent of universal, tragic conflicts, who unified his vast compositions by psychological rather than formal relations. Yet he also broke the architectural system of frieze-like zones, by adopting a symbolic high space in which the figures were grouped with reference to isolated landscape elements. Apollodorus (460-420), Zeuxis (430-390), and Parrhasios (430-?) are credited with the fundamental inventions in the use of local color, light, and three-dimensional construction of figures. Finally ,the proverbial Apelles (370-320) is thought to have developed a convincing and refined coloristic system for the rendering of textures. His flowing sensitive rhythm of composition harmonized those currents of restrained sentiment and emotion that unite gods and men in a self-suffiicient world of their own. Although no work of these painters has survived, the transition from the symbolic, two-dimensional reality of archaic to a direct reflection of reality based on optic illusion can be surmised from literary evidence; reflections in vase painting and later Roman (Pompeian) copies help to complete this theoretical reconstruction. They prove beyond any doubt that the Greeks stopped short of a unified visual illusion. Thus individual figures and objects show correct foreshortening and are often grouped in approximate perspective but never according to a unified scientific perspective. Abstract light and shadow are used to model figures and objects. The coloristic scheme employed is highly differentiated but does not present a consistent application of local color. Objects and figures always retain a sculptural coherence and the color is never allowed to dissolve their outlines. The space is a limited, stage-like setting and there is no attempt to suggest or characterize atmospheric effects. The magnificent effect of the Theseus and the Minotaur, of Achilles and Briseis, of The Battle of Alexander is created by the rhythmic compositional arrangement, by free and easy movement of heroic bodies, and by the lofty psychological interpretation. In consummate rendering of texture and in emphatic expressive strength the painting of the fourth century forged ahead of the contemporary sculpture. Indeed, the sculptor Praxiteles relied upon the painter Nikias to give the finer animation to his statues. We can appreciate the richness and vitality of such painted sculpture in the magnificent "Alexander Sarcophagus" from Sidon.

*Hellenistic.* Geographical horizons expanded and scientific thought quickened in the age of Alexander, but Hellenism does not initiate a new cycle. It is a period of intellectual dispersion and specialization. The Classical concept of an orderly, rational universe is maintained. But the concrete character of the Classic universe that was due to the anthropomorphic character of its ethic religious concepts, is lost. The variety of types in architecture, and of subject matter in sculpture and painting is enormously increased; but this gain is nullified by the loss of intensity which the Classic period achieved by concentrating all its thought and emotions in a few clearly defined types. Art becomes secularized. Hellenistic religious ideals are too abstract to be embodied convincingly in human form, or to be confined residents of narrow temples. Civic architecture, portraiture, genre, and landscape painting are the leading artistic expressions of the new world. Scientific observation aids sculptors to master external appearances and to portray a variety of psychological effects. The individual with his evanescent moods, his immediate physical and emotional reality, dominates the stage. But in contrast to modern realism even the late Greeks were never satisfied with the representation of purely external appearance; like the "Characters" of Theophrastus Hellenistic sculptures always suggest a typical element or experience of the individual. The powerful portraits of Hellenistic Kings from Alexander to Mithridates share an element of superhuman vigor and dynamic power. The Demosthenes, outwardly realistic, stands for the struggle of body and spirit, the Girl of Anzio, for the self-oblivious piety of an adolescent, the Lacoon for heroism before death. The Classical world found its subject matter within itself; the subjects of the Hellenistic world are projected into monsters and barbarians (Pergamon Frieze and the "Large" and "Small" Gauls), or into the world of lower mythology to express very human experiences from the healthy sleep of a rugged peasant (Faun Barberini) to the sentimental petting of courtly lovers ("Invitation to dance", "Eros and Psyche"). Rather

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

than humanize ethical laws Hellenistic art objectifies individual emotions. The abstract ideology of the new world is expressed in personifications and allegories, ("Tyche of Antioch", 300 B.C.) but rarely is the gap between the concept and its embodiment bridged so successfully as in the Victory from Samothrace (ca. 200 B.C.) who sails forth in a jubilant sweep.

Hellenistic painting must also be reconstructed from Roman copies. It was a suitable medium in which to represent the expanded concept of the universe. Space construction was deepened and unified, although the visual illusion was not complete. The representation of light was improved. And the new relation of man and nature was expressed in landscapes which subordinated man to nature (Odyssey, Rome; mosaics, Palermo). The representation of animals, of still life, and of peculiar ethnic types runs parallel to the specialized natural and geographic studies (Dove mosaic, Pergamon). Copies of the Finding of Telephus, of Medea and Her Children show the psychological individualization as it is applied to the mythological sphere; the mosaics of Dioscurides illustrate the bristling vivacity of genre.

The Classical architects had conceived each building as a separate organic unit; Hellenistic architects, accustomed to planning new cities and constructing vast residences, think in terms of architectural complexes (Cos, Pergamon, Antioch, Seleucia, Magnesia). The interest in magnitude overshadows the attention to detail in the temples of Cossutius (Zeus, Athens, 175 B.C.) and Hermogenes (Artemis, Magnesia, ca. 140 B.C.) or in the great Altar of Pergamon (180 B.C.). Their creative efforts are most clearly manifested in secular or semi-secular buildings such as public walks (colonnades in Priene, Pergamon, and Athens), market places, assembly halls (Miletus), libraries (Pergamon), palaces, and ultimately in villas and residential houses. Just as much of Hellenistic sculpture is conceived with reference to a definite architectural setting, so are many Hellenistic buildings planned with reference to other buildings, to architectural zones, and finally to landscape. The contact with the non-Greek architecture of Egypt, Syria, and Mesopotamia influenced the production of new types of buildings (sanctuaries of Egyptian and Oriental gods) and increased the ornamental vocabulary. Conversely, the Greek orders spread into Persia, Bactria, and India. The rhythmic coherence of ornament yields to naturalistic verisimilitude; animal forms join the vegetable motifs. Often the ornaments are conceived as realistic replicas of the actual cult objects (bucrania, garlands, sacrificial implements). Within each building, the objective relation of the tectonic elements comes to mean less than their optic appearance.

It has been argued that Roman art is actually just another phase of the Hellenistic; assuredly the former would have been impossible without the latter. Yet, by the end of the 2d cent. B. C. the unity of Hellenistic art has broken down into a multitude of regional developments. A few migrating artists and workshops showed technical competence; but their products cannot conceal the lack of common aims and ideas; local arts of the Greek lands deteriorated rapidly. Rome restored the political and economic foundations of art and supplied the leading ideas for a fresh start.

Phoenix-like, Greek art continues to provide new inspirations for posterity, because it has encompassed so many eternally human interests, desires, emotions and ideas. In its statues and temples it had accomplished a balance of nature and ideal, of reason and belief, and of emotion and restraint. Greek art is a triumphant affirmation of faith in man as a spectator of the universe and as master of his fate. See J. D. Beazley and B. Ashmole, *Greek Sculpture and Painting,* 1932; L. came many natural and human obstacles during his spectacular career, and eventually was received into Olympus as a demigod. He was usually represented wearing a lionskin and armed with a bow and club. His exploits were extensively treated by 6th and 5th cent. B. C., Greek vase painters, and appeared in architectural sculpture at Delphi (Athenian Treasury), Olympia (Temple of Zeus), Athens (Temple of Hephaestus), and in independent sculpture by Myron, Scopas, Lysippus, Glycon, etc. Pollaiuolo's painting of Hercules strangling Antaeus, the earth giant, gives a spirited representation of him. In post classical sculpture he has been pictured by Bologna, Bandinelli, Pollaiuolo, Canova, Thorvaldsen, Manship, and Bourdelle. —W.R.A.

**HERALDRY.** The art of heraldry includes the designing and authenticating of armorial bearings or coats-of-arms and the preparation of their blazonry, their verbal description in correct heraldic language.

From the earliest times distinguishing emblems and symbolic devices have been worn by individuals and groups in battle, but the essential difference between such symbols and heraldry as now known is the basic hereditary feature of the latter. Present heraldry began in the 12th cent. at the time of the Third Crusade when international participation, combined with the advent of the cylindrical helmet covering the whole face, made identifying marks necessary for recognition in combat, so each knight painted an individual sign on his shield. Later the same device was embroidered on the surcoat worn for protection over his polished armor, from which the term **coat-of-arms** originated. The device was also engraved on the owner's seal used on official documents, whence the study of **sphragistics** (q.v.). These earliest arms, assumed at will by the bearers, were simple bands of color or a single emblem on the shield, often with no symbolic meaning. They were recognized as family property and sons would adopt the same design with a change of color or some added mark of cadency. New grants of arms and judgments of dispute were made by the Kings until 1464 when the Heralds' College was established for designing and granting armorial bearings, together with tracing and preserving genealogies, which it has done from that time to the present.

The emblems pictured on the shield as "charges" came from many sources. Besides those chosen without significance one group includes those which symbolize some valorous deed or momentous event in the life of the original owners, the story often forgotten by his descendants. Another large group is that of **canting arms** or **armes parlantes**, sometimes called **allusive arms**, which are puns of the rebus type on the owners' names. These are sometimes very evident, sometimes far-fetched, sometimes obscure.

After the Crusades many changed their coats-of-arms, replacing some charge of minor significance with a symbol indicating their participation in the Holy War. The most common charge of this type is some form of the cross, of which over 400 varieties have been listed and a score or more are in very general use, such as the cross anchory, cross botony, cross crosslet, cross crosslet fitchee, cross patée, cross moline, cross passion, cross raguly, cross voided. Other Crusade charges include Saracen heads, escallops, coultraps, scimitars and water bougets.

The term **coat-of-arms** can refer either to the shield only, or to the shield and crest, or to the assembly of shield, helmet, torse, mantling, crest and motto, with supporters when granted, all of which together is called the **achievement.** The most important item is **shield** or **escutcheon.** Its shape has nothing to do with the coat-of-arms and is not specified in the blazonry but is entirely a matter with the designer. From the position of the bearer of the shield the side on his right is called the **dexter side** and that on his left the **sinister side.** The arms of unmarried ladies are emblazoned on a lozenge shape and those of churchmen on a vesica.

The **helmet** or **helm**, anciently spelled *heaume*, has changed shape through the centuries from the cylindrical or stovepipe form supported by the head to the type with flanged base supported on the shoulders. The designer must stay in period and not put a 13th cent. helm on a 15th cent. shield. The royal helm is drawn affronté with visor up and the esquire's or gentleman's in profile, closed. To aid in fitting the crest many good designers turn it to a three-quarters position.

The **torse** or **wreath** is a ring of twisted cloth on top of the helmet, covering the joint between helm and crest. It is always drawn with six twists and of the first two colors of the shield. In certain cases a coronet or a **cap of maintenance** is specified in place of a wreath.

The **mantling** is an ornamental flourish issuing from under the torse, originating prob-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

ably from the cloth worn over the helmet to keep the back of the knight's neck from getting sunburned. It again has nothing to do with the **grant of arms** but is purely the artist's fancy and may be elaborated or omitted at will. When emblazoned in color the first two colors of the shield are used.

The **crest** is a specified part of the arms. Starting originally as a device of molded leather or carved wood worn on top of the helmet to identify the bearer in battle it later became a more elaborate ceremonial headdress in pageants and tournaments. Still later when armor was no longer worn it became only a part of the design in so-called **paper heraldry** and many crests were designed that could not have been worn. The careless misuse of the word *crest* to mean coat-of-arms is quite inexcusable.

The **motto**, usually in Latin or Norman French and generally placed on a ribbon below the shield, is a word or short phrase expressing some lofty sentiment or quality of the owner, now and then boastful, sometimes canting, oftener dedicatory. The war cry or *cri de guerre* was an early form, even earlier than heraldry itself.

**Supporters** are animate figures placed one on each side of the shield. In general their use is restricted to the arms of royalty and those of state and municipal corporations.

The **tinctures** include three classes of coverings used on shields, the metals, the colors and the furs. The metals are gold and silver, in heraldic language **or** and **argent**. The usual colors are **gules** (red), **azure** (blue), **vert** (green), **purpure** (purple), and **sable** (black). The commonest furs are **ermine** with black tails on a white ground and **vair**, alternating blue and white shapes representing squirrel pelts.

When a charge is shown in its natural color, which may but need not be other than one of the heraldic colors, it is said to be *proper* and may be charged on any tincture.

**Color symbols.** When arms are drawn or engraved in black and white a universal standard system of line symbols is used to designate the colors. Red is indicated by vertical linings, blue by horizontal, green by diagonals from dexter chief to sinister base, purple from sinister chief to dexter base and sable by crossed vertical and horizontal. Gold is represented by dots and silver is left blank.

**Charges.** The surface of the shield is covered with one of the tinctures, upon which **field** is superposed one or more **charges** of another tincture. The first rule of heraldry is that a color must not be superposed on another color, nor a metal on a metal nor a fur on a fur. Thus a red lion could not be shown on a blue field but could be placed on a gold or silver or ermine field. Sable, however, while classed as a color, is not subject to this rule but may be charged either on a color or a metal. It is often used to represent iron objects.

The **ordinaries** are the oldest and most frequently used of all the charges. Originating no doubt from bands placed across the shield to strengthen it, they form most effective and legible distinguishing marks. They include the **chief**, a band covering the upper third of the shield; the **fesse**, a broad horizontal band across the middle point; the **pale**, a broad vertical band down the middle, the **bend**, a diagonal band from dexter chief to sinister base; the **bend sinister**, from sinister chief to dexter base (rarely used); the **cross**, a combination of fesse and pale; the **saltire** or St. Andrew's cross, a combination of bend and bend sinister; the **chevron**, formed of the lower part of the saltire; the **pall**, the **quarter** and the **gyron**.

**Diminutives** are narrower bands running in the same direction as the corresponding ordinaries. Thus the diminutive of the pale is a pallet, of the fess a **bar**, of the bend a bendlet, of the chevron a chevronel. (Since the bar is a horizontal stripe, and not used singly, there is no such thing as a "bar sinister", in spite of the persistent use of that term by fiction writers.)

The name **subordinaries** is given to a group of charges including the **canton**, a square about 1/5 the width of the shield in the dexter chief; the **inescutcheon**, a small shield in the middle of the large one; the **pile**, the **bordure**, and the **tressure**.

**Parted coats.** The shield may be divided in various ways giving two tinctures in the field. If divided vertically it is *party per pale*. Similarly it may be divided per fesse, per bend, per chevron, quarterly, saltirewise and gyronny.

**Partition lines.** Lines of division and edges of ordinaries may be straight or in one of several patterns, as wavy, indented, invecked, engrailed, etc.

**Common charges.** In addition to the ordinaries there are literally hundreds of devices known as common charges which are superposed either on the field or the ordinary, or both. They may be divided broadly into animate and inanimate classes, the former in-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

cluding animals, birds, fishes, human figures, monsters and parts of each. Single animals must always face the dexter side (except when affronté). Charges may have any tincture, but the rule against putting color to color or metal to metal must be remembered.

The lion is by far the most popular animal charge and the position **rampant** with one foot on the ground and three in the air the commonest pose. Other positions, *salient, passant, statant, sejant, couchant* and *dormant* are seen occasionally. Normally both body and head are in profile, if the head is turned to look directly at the reader he is said to be **guardant** and if looking behind, **regardant.**

The stag is another popular charge and it requires another set of words to describe his positions. If walking, with three feet on the ground he is not **passant** but **trippant** and if looking at the reader not *guardant* but **at gaze.** The boar, the bear, the bull, the horse and a score of other animals are found as charges. Heads of animals, erased, couped or cabossed are quite common. Of birds the eagle *displayed* is best known for its use in the arms of the United States and other countries. The martlet, a swallow with beak and legs cut off is a well-known charge. The dolphin is the commonest marine charge. Fabulous animals called *monsters,* as the griffin, the dragon, the wyvern and the cockatrice are not uncommon.

The inanimate classification covers everything in the vegetable kingdom, astronomical charges and hundreds of traditional artifacts. In the decadent period of the 17th-19th cents. it was made to include such objects as locomotives, steamships, bridges and buildings, now considered as very bad heraldry.

**Blazonry.** To blazon an achievement is to describe it accurately in words and a blazon is this verbal description. To **emblazon,** however, means to paint the arms in full color on paper or other surface. A designer who is asked to use a coat-of-arms in a design would much prefer to have the blazonry given him than a painting or drawing of the arms, which would be only another artist's rendering of it. The good designer knows that heraldry is like etiquette in that one must not make a mistake in it. He not only knows the vocabulary but will avoid any incongruities or anachronisms and should always produce a fine piece of design, sometimes even achieving a work of art.

In the layman's study of heraldry, aside from the appreciation of the beauty of a well-rendered achievement, the ability to read and write a blazon is the most important item. The language may seem stilted and the sentence arrangement peculiar but it is done in the interest of economy of words as well as accuracy. The standard order is to name first the field, then the ordinary, next the charges on the field and finally those on the ordinary. A tincture is named once and afterward referred to by position in the blazon, as "of the field" or "of the second". The descriptions of the crest and motto follow in that order.

It is a mistake to think that heraldry is a dead subject. A working knowledge of it is indispensable to the genealogist, the historian, the architect and the artist-designer. The present use of seals, crests and coats-of-arms by the various branches of the government, the armed forces, states, cities, colleges, guilds and clubs indicates the timeliness of its study by every educated person.

The United States Army has an Heraldic Section under the Quartermaster General, in which all insignia are designed and authorized. This department's rules agree entirely with those of the Herald's College.

One of the interesting applications of heraldry in design is found in British and American armorial bookplates (see ex libris) by master engravers such as C. W. Sherborn and G. W. Eve in England and E. D. French,, J. W. Spenceley and others in America. See Gwillim, *Display of Heraldry*; Whittemore, *Origin and Antiquity of Heraldry*; Fox-Davies, *The Art of Heraldry;* Hope, *Heraldry for Craftsmen and Designers;* Eve, *Heraldry as Art.* —T.E.F.

**Herat rugs.** See ISLAMIC ART.

**Hercules.** See Heracles.

**Hermes** (L. Mercury). The Greek god of fertility and commerce, messenger of the gods, usually represented as a handsome youth with winged helmet and sandals, carrying a herald's staff. On the Greek funerary vases he was often pictured escorting the souls of the dead to Hades. In later art he was the subject of paintings by Correggio and Rubens, and of sculpture by Bologna, Cellini, de Vries, Coysevox, Thorvandsen, Begas, Idrac and Bottiau. —W.R.A.

**heroic realism.** See RUSSIAN ARTS.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**hero legends.** See American Folk Forms, literature.

**Herrera style.** See FURNITURE.

**herringbone.** A decorative pattern in which lines are set diagonally; small parallel lines are set at 45 degree angle with the general direction of the row and at right angles with the lines (or members) of the adjoining rows. —L.T.S.

**hexachordal system.** See MEDIEVAL MUSIC; solmization.

**hibachi** (Jap.). Fire-box or brazier in which a charcoal fire is maintained. An appurtenance of *cha-no-yu* (q.v.).

**hibashi** (Jap.). Fire sticks of metal resembling a pair of chop-sticks, with which charcoal for the fire is handled during *cha-no-yu* (q.v.).

**Hieroglyphics.** The title of a book on Egyptian hieroglyphs supposedly by Horapollo Nilus (4th cent. A.D. ? ), who interpreted them metaphorically and mystically without knowing their significance as a script. This book, together with other Roman writings, was the basis for revival of hieroglyphic studies in the Italian Renaissance. The humanists of the 15th and 16th cents. believed they were imitating the Egyptians when combining isolated images of their own invention so as to convey a secret meaning. Hieroglyphics in their hands became means for the visual representation of poetic epigrams and thereby acted as a stimulus for the development of emblems. —R.B.

**high Gothic.** See Gothic.

**Highland fling.** One of the most ancient Scotch national dances, the Highland fling has for centuries been closely interwoven with the life of the people. It traditionally expresses victory or joy. In form and technique, the dance is perhaps more precise and less subject to improvisation than any other folk-dance. The movement is confined to fast and intricate foot-work combined with clearly defined arm motions. The dance is traditionally a man's solo, accompanied by bagpipe music in 2/4 meter with an almost unvarying, irregular rhythm. —J.G.

**high-level street.** See CIVIC PLANNING.

**high relief.** See relief; relief sculpture.

**high tension porcelain.** See CERAMICS I.

**high warp.** Has its warp placed in a vertical position as a painting is hung.

**high warp loom.** An upright loom; probably the earliest type. The warp is in a vertical position in front of the weaver.

**highway.** See CIVIC PLANNING.

**hilliers.** *Cer.* Cap for sagger (q.v.), same material and shape. See CERAMICS I.

**hill-jar.** A certain form of Chinese Han pottery which has a cover cone-shaped, representing mountain scenery with peaks and valleys and oftentimes hunters and hunted animals. —J.A.M.

**Himejitozan yaki** (Jap.). Pottery made in Harima province.

**Hindu art.** See INDIAN ART.

**Hindu theatre.** See THEATRE.

**Hinnokogi yaki** (Jap.). Pottery made in Yamashiro province.

**hinoki** (Jap.). The Japanese cypress, used extensively as a medium for both architecture and sculpture.

**hip.** (1) The external angle in which adjacent roof-slopes meet each other. (2) A truncated roof or gable.

**hippocampus.** A fabulous monster with head and forequarters like a horse, tail like a dolphin.

**hip-roof.** (1) A roof rising directly from the wall-plate on all sides, and so having no gable. (2) A short portion of a roof over a truncated gable. —J.M.M.

**Hirado yaki** (Jap.). Pottery made in the province of Hizen.

**hiramakie** (Jap.). A lacquer technique. Design in low relief in one plane, produced by successive layers of pure lacquer.

**hirame** (Jap.). A term applied to lacquerware when gold-foil is cut in fragment-like forms, applied to the lacquer surface and, when dry, polished.

**hishaku** (Jap.). A dipper made of bamboo, used to transfer water from the boiling water-kettle to the tea-bowl. A utensil for *cha-no-yu* (q.v.).

HISPANIC AMERICAN LITERATURE. Since none of the Pre-Hispanic native groups of the New World had yet discovered phonetic writing, Hispanic American literature, properly speaking, begins with the colonial period. The various "literary" pieces which undoubtedly existed prior to 1492 were handed down from generation to generation by word of mouth. Hence, in evaluating their merits, whether they be the cryptic Mayan folklore tales or the delicately melancholy verses attributed to the Texcocan King Netzahualcoyotl or the simple Andean lyrics of the kind recited by professional bards at court, in the street or in the market, it is well to bear in mind that most of this stock of poetic or oratorical lore has reached us in Spanish, a fact that makes it difficult to determine the extent to which the original thought and emotions have been faithfully preserved.

In a rapid survey of this sort no attempt at completeness can be made. Often a number of writers or even an entire genre with historical rather than intrinsic significance has been left out. In either case a general statement has been considered enough for the purpose of this discussion.

*I. The Colonial Period (1492-1808).* The first productions in the colonial period were descriptive or epic in character, fraught as they were with the din and clamor of the conquest. This literature takes the form of lengthy reports or still lengthier chronicles, in which the deeds of the conquistadores are mingled with meticulous descriptions of places and peoples. The vastness and novelty of the New World led writers to fix their attention almost exclusively on concrete things. There was little time or predisposition for poetry or a more complex genre such as the novel. These productions were penned by Spaniards who were government officials, soldiers or friars, all of them intent upon revealing to the Old World the wonders of the New. Such are Columbus's letters and memoranda, pervaded with a curious mixture of religious zeal, practical sense and unbridled imagination. Equally vehement are the writings of the "Apostle of the Indies", Friar Bartolomé de las Casas, the renowned author of *Brevísima relación* (1552) and *Historia General de las Indias.*

The conquest of Mexico elicited several long accounts from soldiers and historians. Among these are the five dispatches sent by Hernán Cortés to the Emperor Charles V between 1519 and 1526; the fascinating narrative by Bernal Díaz del Castillo, *Verdadera historia de la conquista de la Nueva España,* whose garrulous style contrasts sharply with the laudatory and methodical account by Francisco López de Gómara, *Conquista de México* (1552). In the first one of these the heroes are the soldiers and horses that came with Cortés; in the other, the conqueror himself, who overshadows all others.

Peru produced the first American chronicler in the Inca Garcilaso de la Vega, whose *Comentarios Reales* (Lisbon, 1609) is the most valuable single work for the study of the Inca period. Garcilaso recreates the imperial splendor of the proud Inca race from which he descended. The author's credulity and pathetic attachment to his subject do not detract from the intrinsic merits of this colorful and eloquent narrative. The conquest and settlement of Peru was one of the most dramatic clashes of two different races ever recorded. Atahualpa's tragic fate and the disintegration of his empire were followed by rivalries among the conquerors. Many accounts of the incidents of the conquest and the subsequent civil wars were written. Among them are the *Historia del descubrimento y conquista de la provincia del Perú* by Augustín de Zárate and the lengthy chronicles by Pedro Cieza de León.

The wonders of the American world were no less fascinating than the conquest itself. It is then natural that a goodly number of observant men should have described the flora and fauna of the new lands. Foremost among them was Gonzalo Fernández de Oviedo, who included a most interesting discussion of American natural history in his *Historia general y natural de las Indias.*

In the deluge of historical writings there appeared the greatest epic poem in the Spanish language: Alonso de Ercilla's *La Araucana,* in three parts (1569, 1578 and 1589). *La Araucana,* written in octaves and under the influence of Ariosto, relates the bloody wars against the indomitable Araucanian Indians of southern Chile. Interspersed with admirable accounts of battles are various interpolated philosophical reflections and arresting scenes of Indian bravery and endurance. The same theme is again presented in Pedro de Oña's *Arauco domado* (1596). Here the attention is focused on the conqueror Don García Hurtado de Mendoza rather than on the Indian warriors, thus making amends for Ercilla's disregard for the Spanish nobleman. This poem, obviously inspired by *La Araucana,* lacks genuine epic inspiration and be-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

trays the author's haste and laudatory purpose.

Two other epics were composed by men who lived in the New World: *La Cristiada* (1611) by Diego de Ojeda, and Bernardo de Balbuena's 5000 octave poem which appeared in 1624 under the title of *Bernardo o victoria de Roncesvalles*.

In the chronicles and poems mentioned there is an evident influence of Spanish literary tradition, which in turn had been nurtured in medieval and Renaissance canons. Throughout the colonial period, literary taste continued to be guided exclusively by the mother country. The most important single influence during the first half of the 17th cent. was that of Góngora, the master of literary preciosity in Spain. Unfortunately, **Gongorism** degenerated, especially in the colonies, into mere intellectual gymnastics. Generally speaking, we find none of the better aspects of Gongorism in the colonies. Banal artificiality contaminated even the better minds. An exception, however, was Sor Juana Inés de la Cruz of Mexico, the lyric poet par excellence in the colonial period. A precocious child, endowed with beauty, charm and intelligence, Sor Juana entered a convent at sixteen seeking "assurance of salvation". Her poetry, intensely human and sincere, betrays the vehemence of a profoundly feminine soul. Her defense of women makes her the first feminist in the American world.

Gongorism did not spare scholars such as the Mexican Carlos de Sigüenza y Góngora (1645-1700), better known as an erudite than as a man of letters, and the learned but erratic Pedro de Peralta Barnuevo of Peru (1663-1743), whom the Spanish critic Menéndez y Pelayo called "a monster of erudition".

In the second half of the 18th cent., new ideas from abroad had a profound effect on intellectual circles in the colonies. A new mentality now existed, the result of contact with foreign scientists, the acquaintance with European works from countries other than Spain and the change in ways of life and customs made possible by the surprising liberality of the Bourbon dynasty. Typical of this new mentality was Pablo de Olavide. A friend of the French encyclopedists, Olavide became the personification of colonial heterodoxy. The expulsion of the Jesuits in 1767, although very detrimental to the continuation of intellectual pursuits, also marks the beginning of a freer age, which was to witness the emergence of native writers and scientists to challenge the principles and modes of life consecrated by centuries of Spanish rule. This new frame of mind is evidenced by Esteban de Terralla y Landa's poem *Lima por dentro y por fuera* (ca. 1792), a satire on prominent men and customs. Very satirical also is one Calixto Bustamante who wrote under the pen name of Concolorcorvo (the swarthy one). His festive spirit strikes a gay note in *El lazarillo de ciegos caminantes* (1773), the story of a long trip, containing keen observations on peoples and customs of the time.

As the 18th cent. draws to a close, symptoms of restlessness are apparent everywhere. The newspapers, social intercourse in the streets and cafes, the discussion of books surreptitiously brought in and the circulation of new ideas on government which had found expression in the American and French revolutions, all these contributed to the increase of the intellectual and social agitation which was to culminate in the wars of independence.

*II. The Struggle for Independence (1808-1824)*. The early years of the 19th cent. were chaotic. Politics and warfare occupied the minds of men. The lengthy composition and the gongoristic poem had given way to the newspaper article on social, political and economic questions. The literary and artistic societies founded by men born in the colonies became plotting centers which attracted the best men of the time. Aside from scientific articles like those of Francisco José de Caldas of Colombia and a great abundance of patriotic poetry, this period was not productive of first rate literature. There do abound, of course, political manifestoes and proclamations, some of them written by the greatest men in Hispanic America. Many of them had studied in universities under the impelling force of late 18th cent. enlightenment. Among the outstanding political thinkers of that day is, of course, the Liberator Simón Bolívar. His celebrated *Letter from Jamaica* (1815) is a rare example of penetrating insight into the future of the newborn republics.

A representative prose writer of this period is José Joaquín Fernández de Lizardi (1774-1827), the author of the first Hispanic American noval: *El periquillo sarniento* (1816). In true picaresque fashion the hero of this didactic narrative passes from one adventure to another, thus affording the author an opportunity to point out the virtues and defects of contemporary Mexican society. Also a journalist, Fernández de Lizardi was a bold

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

defender of the revolutionary cause. His contributions, published under the pseudonym of "The Mexican Thinker", helped notably to keep alive the spirit of revolt in his country.

With the rapid multiplication of periodicals and the appearance of a new reading public, there developed a taste for popular poetry. One of its manifestations is **gaucho poetry**, a sort of continuation in America of the Spanish popular ballad. Among the earliest cultivators is the Uruguayan Bartolomé Hidalgo, whose heroic verses (*Cielitos heroicos*) set a pattern that was to evolve into noteworthy literary works.

In 1824 Hispanic American independence was assured with the great victory at Ayacucho. With the return to a fair degree of normalcy literary life began anew.

*III. The Romantic Age (1824-1888).* FORERUNNERS. Romanticism reached different parts of Hispanic America at different times but some of its literary accessories are present in Mexico and Argentina in the period immediately following independence. Among the forerunners of Romanticism are two great poets: José Joaquín Olmedo of Ecuador (1790-1847) and José María Heredia of Cuba (1803-1839). Olmedo's best known work is the poem *La victoria de Junín: Canto a Bolívar* (1825), a resounding tribute to the Liberator. In it grandiloquence blends with imagination, sonority with vehemence. Heredia, better known than Olmedo, was a standard bearer of Cuban independence and the majestic singer of nature's moods. His odes *En una tempestad* (1822), *Al Niágara* (1824), *Al sol* (1830) and his mediative poem *En el Teocalli de Cholula* (1820) all have a ring of sincerity and genuine inspiration.

Contemporaneous with these pre-romantic exponents of Hispanic American spontaneity and poetic arrogance there rose a smaller group of "classicists". The greatest of them all was Andrés Bello (1781-1865), a scholar and a patriot born in Venezuela and later an adopted son of Chile. A poet and a grammarian, a philosopher and a jurist, Bello stands out as the personification of the self-restraint and method of a first rate humanist. His *Gramática castellana* and his literary investigations reveal the breadth of his preparation. His poetry, original and translated, bespeaks the sensitiveness of the scholar's heart. But like a mighty torrent Romanticism broke all dikes. This occurred after the epoch-making polemic between Bello and the brilliant and pugnacious Argentine exile and journalist, Domingo Faustino Sarmiento (1811-1888).

Sarmiento, a schoolmaster and outspoken foe of the tyrant Rosas, had arrived in Chile to earn his living as a newspaper writer. He was tender in his affections and uncompromising in his hatred. Sarmiento became the champion of civilization. He waved aside with disdain everything that smacked of lifeless conservatism. His magnetic personality fired the South American intellectual world. He had the reformatory and progressive spirit of a convinced romanticist. His best known work is *Facundo, o la civilización y la barbarie* (1845). This is a pitiless condemnation of the tyrant Rosas and of his henchmen, symbols of barbarity, ignorance and oppression. Back in Argentina after the fall of Rosas (1852), Sarmiento was successively deputy, senator, minister, governor and eventually president of the republic.

PROMINENT ROMANTICISTS. By the middle of the 19th cent. romanticism had spread all over the Hispanic American world. In point of time in this sketch, first place belongs to the Argentinian poet Esteban Echeverría, the author of *La cautiva* (1837). This poem is the dramatic story of a married couple and their son who had been captured by Pampa Indians. Its best asset is the description of Pampa scenes. Also a relentless enemy of Rosas, Echeverría compared in *El matadero* (a sort of novelette) the barbaric practices of the tyrant with the carnage of a slaughter house.

Other distinguished romanticists were the exemplary and exalted Colombian citizen, José Eusebio Caro, an intense reformer and thinker; Julio Arboleda, also a Colombian and a champion of liberty, whose verses, though not abundant, show deep sentiment and refinement; the unfortunate "Plácido", the Cuban mulatto of tragic memory; the Cuban Gertrudis Gómez de Avellaneda, whose verses tell of the disillusion and despair of a passionate soul; the somber Manuel Acuña who ended his own life at twenty, and Juan de Dios Peza, the Mexican, whose verses, full of devoted love, made him very popular at the time.

Romanticism held sway until the end of the century, long after it had died away in Europe. This is proved by the late appearance of productions like Juan Zorilla de San Martín's *Tabaré* (1888). In it the author proposed to delve into the ancestral soul of the Uruguayan native, the Charruan Indian. Like many other pieces of **Indianist literature**,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

*Tabaré* is a sentimental conception of the Spanish American native.

Not a few romantic novels with Indianist themes show a marked influence of foreign authors: Chateaubriand, Scott, Fenimore Cooper. In them the Indian is endowed with a sensitiveness and refinement he did not have. A novel of this type is Juan León Mera's *Cumandá* (1871). On the whole only mediocre works are found in this Indianist genre.

The greatest of all the romantic novels is Jorge Isaacs's *María* (1867), a sweet and tender story that all generations have read. The delicacy of sentiments and idyllic beauty of this tragic romance have impressed millions of young readers. Also popular, although inferior to *María,* is José Marmol's *Amalia* (1851-1855), an absorbing love story with Rosas's tyranny as its background. A unique romantic variation in prose is the historical "tradition". Unequalled in this type of short story is Ricardo Palma of Perú. His *Tradiciones persuanas* have had many imitators but none that matched his wit and charm.

Love for the unspoiled simplicity of the country people led Argentinian romanticists to turn their eyes to the gaucho as Hidalgo and others had done before them. This **gaucho literature** was popular in form only. Its cultivators were men from the cities. Among them are Estanislao del Campo, author of *Fausto* (1866) which relates the impressions of a simple gaucho at a performance of Gounod's opera, and Hilario Ascasubi, whose *Santos Vega* (1872) recounts the life of a gaucho troubadour. But the most notable gaucho piece is José Hernández's *Martín Fierro* (1872 and 1879), a poem which has been called "the epic of the Argentine".

The influence of such Spanish **costumbrista writers** as Larra, Mesonero Romanos and others gave rise to cultivation of the short narrative of customs which later developed into the full length realistic novel. Again, in the latter genre, the influence is Spanish, through authors like Pereda and Pérez Galdós. An important figure in this field is Alberto Blest Gana, who describes Chilean manners in *Martín Rivas* (1862) and the foibles of his fellow countrymen living in Paris in his masterpiece, *Los trasplantados* (1904). In Mexico, Ignacio Manuel Altamirano, José López-Portillo and Rafael Delgado portray Mexican society of both the city and the country. It is in Colombia, however, that realism produces the greatest number of works. At least passing mention should be made of *Manuela* (1866) by Eugenio Díaz, and *Pax* by Lorenzo Marroquín. The acknowledged master of Colombian realism is Tomás Carrasquilla who links one century to another. Among his works are *Salve Regina* (1903), *El padre Casafús* (1914) and his best work, *La marquesa de Yolombó* (1928), in which he has given us a study of social life in Antioquia.

In the latter part of the 19th cent. French naturalism won a few followers. This school still exists at the present time. Although scientific determinism was very much discussed in Hispanic America it did not produce truly great works. Among the better ones are *Sin rumbo* (1885) and *En la sangre* (1887) by Eugenio Cambaceres of Argentina; *Las honradas* (1917) and *Las impuras* (1919) by the Cuban Miguel de Carrión and the several novels of the Mexican Federico Gamboa, such as *Suprema ley* (1896), *Santa* (1903) and *La llaga* (1912). The vitality of the genre is attested by the late appearance of *Juan Criollo* (1927) by Carlos Loveira of Cuba ,a naturalist with all the makings of a great novelist. This work is a penetrating analysis of Cuban traits.

The tempo of cultural and political life in the latter part of the 19th cent. is best revealed by the essayists. Some of them, like Cecilio Acosta of Venezuela and Juan Montalvo of Ecuador were champions of liberty. Each in his own way resisted tyranny. Of the two, Montalvo is the greater man as a literary figure. His breadth of thought, mental loftiness and impeccable style make him inimitable. Most representative of his works is the collection entitled *Siete Tratados,* written about 1873. His indomitable spirit and contempt for mediocrity and narrow-mindedness led him to write the burning pages of *Mercurial eclesiástica* (1884) and *Catilinarias* (1894).

Peru also had a great essayist and leader in Manuel González Prada. The defeat of Peru in the War of the Pacific (1879-1883) aroused this author's civic ire. He organized the youth of Peru and proceeded to tear down the old order mercilessly. His *Páginas libres* (1894) and *Horas de lucha* (1908) mark the birth of a new national consciousness. His example was to be followed later by the Aprista group under the leadership of Víctor Raúl Haya de la Torre.

Less spectacular but just as much imbued with reformatory zeal, the Porto Rican Eugenio María de Hostos energized the American world with his exemplary life and inspired teaching. In Santo Domingo, Porte

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Rico, Chile and other countries, Hostos preached the doctrine of orderly social conduct and enlightenment. His best work is *Moral social* (1888), a call to order and social morality in accordance with the laws of Nature.

*IV. Modernism (1888-1910).* The last quarter of the 19th cent. witnessed a profound literary reform, the most important ever to originate in Hispanic America. The rise of a liberal middle class, the prevalence of positivism in intellectual circles and the spread of realism and naturalism in literature gave rise to "Modernism". This was a personalistic and aristocratic counter-current in poetry which was none the less a symptom of the general awakening in all spheres of intellectual and social life. Modernism sought above all the creation of beauty, the untrammeled expression of personality and the rejuvenation of the Castilian language. Modernism was aesthetic in its import and cosmopolitan in its scope. It fused together Romanticism, Parnassianism and Symbolism, thus holding in one channel widely different literary currents which in Europe had been non-contemporaneous and even antagonistic. This unification can be seen in the poems of the precursors of the movement: musicality in José Asunción Silva, objectivity in Julián del Casal and a marked elegiac tone in Manuel Gutiérrez Nájera.

The publication of *Azul* (1888) by Rubén Dario, the greatest figure within Modernism, marks the year of definition and self-assertion. This volume was followed by the sumptuous *Prosas profanas* (1896), (the apogee of Modernism), and the more human *Cantos de vida y esperanza* published in 1905. The variety and exquisiteness of Dario's moods, his sincerity and devotion to art, made him the pivotal center of the new school, In later years his aristocratic aloofness gave way to a more universal note. He left his ivory tower and sang of the cares and sorrows of man. Darío's influence in the Spanish speaking world was tremendous. With him, Hispanic America is incorporated into world literature.

Modernism was as varied as were its cultivators: sonorous and epic with José Santos Chocano of Peru, philosophical with Guillermo Valencia of Colombia, spiritual and devout with Amado Nervo of Mexico, refined and self-assertive with Salvador Díaz Mirón, also of Mexico. Argentina contributed the versatile Leopoldo Lugones and Uruguay the neo-gongoristic Julio Herrera y Reissig. Finally in 1911 Enrique González Martinez sounded the death knell of the school in his poem *Tuércele el cuello al cisne.*

Hispanic America also had one great modernist in prose, the Uruguayan thinker José Enrique Rodó, best known for his essay *Ariel* (1900). Written shortly after the Spanish-American war, this long discourse voiced a new credo of life and conduct which gave Hispanic America a sense of self-respect. The analysis of Hispanic traditions—in contrast with North American ideals and accomplishments—is not always sound, but Rodó's olympic attitude and impeccable style made *Ariel* one of the most widely read essays. *Los motivos de Proteo* and *El mirador de Próspero* are also indispensable for an understanding of this Emerson of South America.

*V. The Contemporary Period (1910-1943).* Post-Modernism preserved the worthwhile values of Modernism. It veered off, however, into various new directions, now striving for simplicity and deeper human content, now going back to nature and common every-day life. Some representative figures in this school are Manuel Magallanes Moure of Chile, Enrique Banchs, Fernández Moreno and Arturo Marasso of Argentina, Emilio Frugoni and Carlos Sabat Ercasty of Uruguay, Luis Carlos López and Miguel Angel Osorio of Colombia.

The most significant development within Post-Modernism is the appearance of several poetesses: Gabriela Mistral of Chile, sad and sweetly maternal; Alfonsina Storni, disillusioned and ironic; Delmira Augustini, passionate and fanciful, and María Eugenia Vaz Ferreira, a woman of intelligence and pride. The most captivating of them all is Juana de Ibarbourou, poet laureate of Hispanic America.

A still greater refinement was achieved in more recent years by such artists as José María Egurén of Peru, Emilio Oribe of Uruguay and Ramón López Velarde of Mexico, to mention only three of a much larger group. Among the latest poets the most significant are Pablo Neruda and Vicente Huidobro of Chile, Javier Villaurrutia of Mexico, the Ecuatorian Jorge Carrera Andrade, Carlos Pellicer of Mexico and César Vallejo of Peru. At least passing mention should be made here of Negro verse. Its most significant cultivators are Nicolás Guillén and Emilio Ballagas of Cuba and the Porto Rican Luis Palés Matos.

In the novel, Hispanic America has in recent years produced some truly outstanding

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

works. The relation of man to the land he lives on is masterfully presented by Rómulo Galiegos in *Doña Bárbara* (1929). Before him, José Eustacio Rivera of Columbia had written the odyssey of man in conflict with the monstrous in nature. His novel, *La vorágine* (1924), is the best of the jungle novels. Other writers turned their eyes to the great convulsion of the Mexican revolution. Chief among them is Mariano Azuela. His novel *Los de abajo* (1916) is considered one of the best in the contemporary period. In Argentina the gaucho theme blossomed anew in Ricardo Güiraldes's *Don Segundo Sombra* (1926), which is a poetization of the pampa and the gaucho. The prosaic *peón,* a descendant of the independent gaucho of old, has been studied in the works of Justino Zavala Muniz of Uruguay and Benito Lynch of the Argentine. The re-discovery of the common man has brought the Indian and the Negro to the novel: the Mexican Indian in Gregorio López y Fuentes's *El indio* and Mauricio Magdaleno's *El resplandor;* the Andean Indian, in Jorge Icaza's *Huasipungo,* a pitiful story of the native of the Ecuatorian mountains. Among the most recent works of the latter type is Ciro Alegría's *El mundo es ancho y ajeno,* awarded first prize in the Latin American novel contest of 1941.

Among the writers of psychological novels none compares with Eduardo Barrios of Chile. His *Un perdido* and *El hermano asno* have justly made him famous. In Argentina, Manuel Gálvez has also studied various phases of city life in *El mal metafísico,* one of his best novels, and in *La maestra normal* and *Nacha Regules.* His last few novels are inferior, particularly those that followed his trilogy on the war with Paraguay.

Opposed to the novel of the ordinary man is the novel of "evasion", as the Peruvian critic Luis Alberto Sánchez has called it. Its themes are bygone days, the spell of foreign lands and the world of dreams.

In the short story not a few writers have achieved distinction. Among them are: Ventura García Calderón, a master in the recreation of legendary and mysterious Peru; Horacio Quiroga, tormented and bordering on insanity, the interpreter of the mysterious and of impending fatality; Mariano Latorre of Chile, a landscape painter; the lamented José de la Cuadra of Ecuador and the prolific Javier de Viana of Uruguay.

In contrast with the abundance of fictional literature is the scarcity of dramatic productions. In most countries the drama has appeared only sporadically. A notable exception is Argentina where the Teatro del Pueblo, ably directed by Leónidas Barletta, has kept alive the interest in native and foreign drama. The best known of the Hispanic American dramatists is Florencio Sánchez, the initiator of the modern theater in South America and a keen observer of rural life and native types. The dominant notes of his plays are accurate observation and a marked feeling of compassion.

In the ideological field, Hispanic America is becoming better known through its essayists. Aside from the older thinkers like José Vasconcelos, Francisco García Calderón, Alejandro Deustua, Enrique Molina, Alejandro Korn, Enrique José Varona, Carlos Vaz Ferreira and brilliant Alfonso Reyes there are several younger groups that have made themselves known. In Argentina there is the group gathered around the indefatigable Francisco Romero. Important too is the Aprista group of Peru, which inherited the combative spirit of Manuel González Prada. Still others are discovering the personality of their own country or that of their neighbors: Ezequiel Martínez Estrada of Argentina, Jorge Mañach of Cuba, Luis López de Mesa of Colombia, Mariano Picón Salas of Venezuela, to mention only a few.

The visits of noted European thinkers and more recently the arrival of European refugees have contributed to the creation of an even greater interest in various fields of intellectual endeavor. The present world conflict has also had profound repercussions. Hispanic America is now living its hour of decision. Its intellectual and artistic potentiality will be revealed in the years to come.

**history of art.** A subject of study in the general field of the "humanities", concerned with the graphic and plastic arts; primarily sculpture, architecture (including city planning), and painting in oil, tempera, fresco, water color, encaustic, ink, etc.; and secondarily the minor arts, crafts, applied arts, and industrial arts—including prints and drawings, manuscript illumination, mosaic, stained glass, ivory carving, wood carving, metal work and jewelry, ceramics, textiles, tapestries, printing, book binding, weaving, basketry and varied peasant crafts, ornament, lettering, furniture, interior decoration, costume design, advertising and industrial design, photography, and the cinema.

The study of the history of art involves, in the first place, the usual historical approach. Periods, styles, movements, schools, and individual artists and works of art are investigated in historical perspective; and the attempt is made to discover correct dates and chronology, proveniences, sources, interinfluences, authorship, authenticity, biographical data and relevant documentary facts, iconography, and cultural and social contexts. This research combines the scientific accuracy and objectivity of archeological investigations and the philosophical discipline of theoretical interpretation. In some periods the study of art provides the chief source of historical knowledge, and the contribution of this subject to general history is always important to the extent that it succeeds in its essential purpose, viz. to reveal and interpret the past through the visual records of its emotions, thoughts, ideals, and aspirations.

The modern art historian, however, is more than a cataloguer or statistician of historic fact, and more than an interpreter of historic meaning in an objective, scientific sense. Ideally art history today leads to connoisseurship (q.v.), which may be attained only with the development of critical sensitivity through discipline in aesthetic judgment. This involves analytical studies in the formal aspects of the visual arts, the language of expression, the analysis of content; and it requires a systematic investigation in the philosophy and psychology of art. The true art historian, as connoisseur, is thus professionally versed in that which is genuine, rare, and choice in the field of art, both in the past and in the present. He is capable of re-creating in verbal terms the true and unique meaning of individual works of visual art of any age, not only in terms of the historical and cultural context, but also in terms of the individual ideas, experiences and insights of the artist. And finally, the art historian, as connoisseur, is competent and obligated not only to interpret the aesthetic meaning, but also to appraise the aesthetic merit of works of art in terms of their broad philosophical or human significance.

Arising out of the simple archaeological studies of the 18th and 19th cents., the history of art has not always recognized the comprehensive obligations it now assumes. Modern art history is a complex study, in part scientific and objective, in part philosophical and normative, involving an attitude at once historical, analytical, interpretative, and judicial. Moreover, the zealous historian of the arts today understands the implicit needs of contemporary life and art, and, as the historian of political theory constantly is mindful of his contribution to contemporary practice, so the historian of the arts increasingly exercises his judicial function in a salutary and responsible endeavor to quicken and inform both the artist and the amateur of the arts. See ARCHAEOLOGY, AESTHETIC ASPECTS OF. —L.D.L.

**history of music.** See music history, periods in.

**hitsui** (Jap.). Brush stroke.

**Hizen yaki** (Jap.). Pottery made in Hizen province.

**ho** (Ch.). Sacrificial bronze vessel. Three hollow legs, handle at side, spout and cover. Used for mixing sacrificial drinks. See SYMBOLISM IN FAR EASTERN ART.

**Hobbyists, the.** See FRENCH ART; Dadaism.

**hocket** (hoquetus). See MEDIEVAL MUSIC.

**hogan** (Navaho, house). A dwelling built of logs set upright like a tripod or laid horizontally in courses on a hexagonal plan, covered with poles, bark and a thick layer of earth. A smoke hole is left at the apex, and an opening is left for a door, usually on the eastern side. The hogan is used by the Navaho chiefly in winter for protection from the cold and for storage. —H.G.

**Hohenstaufen art.** This period parallels almost entirely the reign of the German Hohenstaufen Dynasty (1138-1254). It is noted for its psychological tensions and artistic antagonisms. The proper trend of Hohenstaufen art suffered from a great deal of opposition which makes the whole picture difficult to review but which also makes it very interesting.

Generally speaking, one may say that the Hohenstaufen period was interested in human individuality, in centralization and in rationalization, and, because of that, has been called the **proto-Renaissance** or the predecessor of the Renaissance.

There were three characterizing attributes in the architecture of this period: first, an inclination toward the circular plan, which means that all peripheral parts of the building are placed around a dome as center; secondly, an anti-Gothic handling of vault and wall, which means that the pressure of the vault was placed upon the wall from which had been taken those parts not immediately necessary for the support of the pressure; thirdly, a final effect which was picturesque and which was accomplished in an ecclectic manner.

The Hohenstaufen architectural period begins with the two-storied building in Schwarzrheindorf near Bonn (begun in 1151). The ground plan was a Greek cross. Examples of this period are the rebuilt cathedral in Speyer (second half of the 12th cent.), the eastern portions of the Church of the Apostles in Cologne (after 1192), the eastern portions of the Cathedral of Strassburg (after 1176), the Cathedral in Worms (end of the 12th to the beginning of the 13th cent.), the dome of St. Gereon (1219-1227), the choir of the Church of Our Lady in Gelnhausen (1230-1250), the Abbey of St. George in Limburg-Lahn (about 1235), the west choir of the Cathedral in Mainz, (beginning of the 13th cent. to 1239), the west portion of the Abbey of St. Patroclus in Soest (the end of the 12th cent. to 1220), the ruin of Heisterbach (1227), and the Kaiserpfalz in Gelnhausen (beginning of the 13th cent.).

Examples of the reactionary movement against the Hohenstaufen style are ,among others, St. Michael in Altenstadt near Schongau, (2d half of the 12th cent.), the eastern portion of the former abbey of the Benedictines in Murbach, in upper Alsace (about or shortly after the middle of the 12th cent.), the abbey of the Scottish monks of St. Jacob in Regensburg (about 1180), and the former Praemonstratenser Abbey in Jerichow (1144-1250).

In sculpture, special importance was given to the representation of the human figure. Two opposing conceptions are to be noticed. The followers of the one trend started from a metaphysical aspect as the predominant view of life, the others from a natural, human aspect. Both divisions were split into two, or even more, specialized groups. Among the representatives of the metaphysical viewpoint there was one strongly conservative group which clung to the old Salian ideals, and sometimes overdid the Salian attributes to the point of rigidity. Examples of this trend are: the limestone relief in the former abbey in Oberpleis (about 1151), the Imerward Crucifix in the Cathedral of Braunschweig (3d quarter of the 12th cent.), the statue of Mary and Child in Hoven near Euskirchen (about 1175), the tombstone of Plektrudis in the crypt of St. Maria im Kapitol in Cologne (last quarter of the 12th cent.), Mary and St. John at the Crucifixion from the Abbey Sonnenburg near Bruneck (about 1200), now in the Schnuetgen Museum, Cologne. The second of these metaphysical groups stressed the emotional movement of the soul, ranging from soft emotions to ecstacy. Examples of this group are: the stone relief of Daniel in the Lions' den in the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Cathedral of Worms (last quarter of the 12th cent.), the Madonna of Dom Ruppert from St. Laurentius, in the Luettich Museum of Archeology (last quarter of the 12th cent.), and the Mary of the Wessorbrunner choir chancel (about 1250), now in the Bayrisches National Museum, Munich.

Examples of the ecstatic group are: the Gero Crucifix in the Cathedral of Cologne (about 1180), and the Tympanon relief in the Cathedral of Trier (third quarter of the 12th cent.). The other trend in sculpture in which importance was put upon the more natural-human aspect was also divided into two different groups. One group emphasized the dependence of the human body upon certain natural laws which are the activating principle of bodily life. But these laws, and therefore the human body, are dependent upon the metaphysical aspect to which they are subject. This was a pre-Gothic conception. The other group, however, stressed the point that the human body is independent of the metaphysical, that it follows its own natural laws and therefore is self-sufficient. This latter group may be called Hohenstaufen in the proper meaning of the word. The reliefs of the choir chancel in the Church of Our Lady in Halberstadt may be considered as the point of origin of the two aspects.

Examples of the pre-Gothic group are: the figures of the Prophets and Apostles on the reliquary of the Magi in the treasury of the Cathedral of Cologne (1206-1230), the prophets and apostles on the porch of the Prince's Portal of the Cathedral of Bamberg (about 1220-1230), the reliefs on the choir chancel of Bamberg (1220-1230), and the reliefs on the reliquary of St. Elizabeth in Marburg (about 1236-1240).

Examples of the true Hohenstaufen style are: the statues on the gilt porch of the Cathedral of Freiburg in Saxony (about 1230), the Bamberg Equestrian and the statues of the Adam Porch in the Bamberg Cathedral, the statues of the so-called Sibyl and of Mary in Bamberg, the reliefs of the Passion on the choir chancel in Naumburg and the statues in the west choir of the Naumburg Cathedral (about 1250), and the reliefs and statues of the south portal of the Cathedral in Strassburg (1240-1250).

In the field of painting there were similar opposing trends. The Hohenstaufen style in its true objective endows the human figure with a self-sufficient, innate human dignity. This line begins with the murals in the lower church in Schwarz-Rheindorf (1151-1156), and is continued in the murals on the vaults of the chapter house of the former abbey of the Benedictines in Brauweiler near Cologne (about 1174). Striving toward the same goal are the enamel paintings on the casket of St. Heribert in Deutz and the enamel paintings by Nicolaus Virdunensis, in the Abbey of Neuerburg near Vienna, (1181), the paintings on the ceiling in St. Michael in Hildesheim (late 12th cent.), and the murals on the west choir in the Cathedral of Gurk (about 1220).

The combination of the natural bodily aspect with spiritual emotion is shown in the murals of the Baptistry of St. Gereon in Cologne (2d quarter of the 13th cent.), and in the murals on the choir of the Church of Our Lady in Gelnhausen (1240-1250). Those painted from a purely metaphysical point of view are: the miniatures of the Evangeliar from Gengenbach (about 1150), the illustrations in the "Scivias" tractate of Hildegard of Bingen (2d part of the 12th cent.), and murals of the choir of St. Maria zur Hoehe in Soest (about 1230), which belongs to a more visionary and ecstatic part of this metaphysical group. At the end of the Hohenstaufen epoch a strongly agitated and baroque style was developed, as can be shown in the illustrations of the Missale of Halberstadt (about 1250), which shows a Byzantine influence, in the illustrations in the Psalter of Baumont, (after 1250), and in the illustrations of the *Liet von der Maget* by Wernher von Tegernsee (after 1200).

**Hohokam art** (Pima, ancient ones). The culture of the Hohokam, though contemporary with that of the Anasazi (q.v.), is less well known because less intensively investigated. They lived in the desert lands of southwestern Arizona, whither they may have migrated from the south, probably in the early centuries of the Christian era, with a culture pattern already established. The evolution of this culture in its new habitat seems fairly clear in its general outline. At first they built rectangular pit and surface houses, of the single unit type, with walls of brush, poles and mud, which were grouped into walled villages spread widely over the arid valleys. Agriculture was basic in their economy because of extensive, ingenious systems of irrigation. Hence they are sometimes called the Canal Builders. All through their history, pottery was one of the most important of the arts and was produced in great abundance. The most characteristic shape was a large jar with a low, broad shoulder, built up by coiling but finished by the paddle and anvil technique; that is, smoothing the coils by beating them with a paddle on the outside, against a stone held on the inside, instead of smoothing with a gourd tool, the usual method in Pueblo pottery making. Designs in red upon the buff surface consisted of vigorously drawn rectangles, containing hatchings, frets and zigzags apparently derived from textile design, varied with bold spirals. A less well known but unique ware consists of bowls with decorations of representational content, figures of men, birds and animals freely sketched in a style quite different from the abstract quality of Pueblo pottery decoration but akin to that of the Mimbres potters (q.v.).

This early stage was followed by a concentration of villages which may have prefaced an invasion of Pueblo peoples from the north, lasting from ca. 1300-1350 to ca. 1400-1450 A.D. Communal dwellings of adobe with many stories appeared alongside the one-story surface houses of the earlier type. Together they constituted a compound surrounded by a wall with no opening and entered by a ladder. Casa Grande, now in the Casa Grande National Monument, affords the best example. Cliff dwellings were also built.

The Hohokam were unique in the Southwest in their use of shell, probably obtained from the Gulf of California. From it they carved and engraved necklaces, rings, bracelets and pendants in the form of or decorated with lively figures of frogs, sheep, birds and humans, both for personal adornment and for burial purposes. These all show a sense of essential form and decorative value. Fragments reveal a skill in weaving fine cloth with intricate patterns closely related to ceramic ornament.

After about a century of invasion the northerners appear to have left. Their influence is still seen in the communal type of building which continued alongside the original type and in the appearance of a polychrome pottery, which, however, did not supplant the characteristic red on buff ware.

What became of the Hohokam is not known. The historic Pima and Papago tribes are believed by some to be their direct descendants. But that is a moot question. See Charles A. Amsden, *An Analysis of Hohokam Pottery Designs,* in Gila Pueblo *Medallion Papers,* No. 12 (Globe, Arizona, 1936); Harold S. Gladwin et al., *Excavations at Snaketown,* in *Medallion Papers,* Nos. 25-26 (Globe, Arizona, 1937); Frank H. H. Roberts, Jr., *A Survey of Southwestern Archeology,* in Smithsonian Institution Annual Report, 1935; George C. Vaillant, *Indian Arts in North America,* 1939. —H.G.

**hold** (It. *fermata*). *Mus.* A note or a rest prolonged.

**hollow relief.** See relief sculpture.

**homespun.** (1) A loose but very strong and durable woolen, woven on hand looms. (2) A coarse and loosely woven material, made in imitation of actual home made cloth. Irregularity of mixed colored yarns is main characteristic, also rough finish. —G.W.R.

**homophony.** Process of composition by which one melodic line is presented simultaneously with an accompaniment of chords, or the intervals formed by several simultaneously presented melodic lines acquire the character of chords subject to the principles of harmony, one of these lines usually standing out as a dominating element. —E.K.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**honzon** (Jap.). Principal sculptured image in a Buddhist temple.

**Hoo** (Jap.). Bird of good omen. A long-tailed pheasant type of bird commonly called the phoenix. See "Phoenix in Fact and Fancy", by Alan Priest, *Bull. Metropolitan Museum of Art,* New York, Oct. 1942.

**hooked rug** (drawn in). Originated and practiced by prehistoric workers for clothing and later by poor people to give warmth to bed and covering for damp bare floors. A tufted rug made on a foundation of burlap or linen. The pile is made of long narrow strips of cloth or yarn which is pulled into the foundation by means of a hook, leaving an uncut loop on the surface of the foundation. The loops can be cut with rug shears after the drawing in process is complete. Many colors and patterns are possible. —B.E.J.

**hoop.** See JEWELRY.

**Hopewell culture.** An aboriginal American culture centering in southern Ohio but widespread in the eastern United States. Its name derives from the owner of a site near Chillicothe, Ohio, where remains of it were first discovered and where some of its finest products have been found. See Eastern North American Aboriginal art. —H.G.

**Hopi art.** The Hopi (the name a contraction of the Hopi *Ho-pi-tu,* peaceful people), formerly called Moki or Moqui, are an isolated tribe living in nine villages on three mesas which jut out like headlands from the Black Mesa toward the Painted Desert of north central Arizona; one valley village lies to the west and several modern towns have sprung up at the foot of the mesas. Best known are Walpi on First Mesa, and Oraibi on Third. The origin of the Hopi is not known with certainty. They differ racially from the other Pueblos, being of Shoshonean stock, except the inhabitants of Hano, a Tewa village on First Mesa, settled ca. 1700 A.D. At first they appear to have lived at the base of the mesas, choice sites because of springs; later, for protection against raiding nomads, they moved up on the mesas, where their stone and adobe houses and kivas are crowded along the ridges of the steep-walled headlands. Because of their inaccessibility the Hopi have retained their ancient cultural pattern more nearly intact than other tribes. They are expert farmers. Their fields of colored corn, beans and squash, and their orchards of peaches, a gift of the Spaniard, stretch many miles from the mesas. From prehistoric times they have been fine craftsmen and their wares have been in demand for trade along ancient routes. Their ceremonials are most elaborate and require for their preparation and celebration a large amount of time and activity, and are a determining factor in many of the crafts. These ceremonials involve drama, costume, song and dance, and their function is not amusement but a ritual, prayers for rain, for increase in crops and for the welfare of the tribe. The kachina (q.v.) cult involves a continuous ceremonial with masked dancers, lasting from January to July. The unmasked dances, such as the Snake and Flute, take place during the remaining six months. Kachina dolls, representations of the kachinas, are carved by the men from cottonwood, painted, and decorated with feathers and other embellishments in imitation of the costumes of the dancers. They are given to the children by the kachinas at the time of the dances or are hung up in the houses for ceremonial purposes.

Basketry is a craft of the women. Plaques and bowls for both household and ceremonial use, and, recently, deep baskets for trade, are made of local grasses, stems, yucca and twigs, and decorated with geometric motifs or human and animal figures highly conventionalized and adapted to the shape and weaving technique. Styles differ on the different mesas. Second Mesa produces a thick oil product; Oraibi and Third Mesa a fine type of wickerwork.

Pottery, also a woman's craft, was made in all the villages in prehistoric times, a black and white ware common to the Pueblo region. The contribution of the Hopi to the ceramic art of the Southwest was the development of a polychrome style which culminated in the Sikyatki ware (q.v.) of Pueblo IV period (see Pueblo Art). It was made on First Mesa, where the pottery craft was concentrated. The shapes consisted chiefly of large bowls with a broad flattened shoulder, an excellent surface for decoration, and shallow bowls with decorations on the interior. The decorative motifs, in red and brown on a yellow or orange base, consist of geometric shapes and highly conventionalized birds and animals. In shape, color, and the bold vigor of its decoration this ware is an outstanding ceramic product of the Southwest.

Weaving was a craft practiced by the men. Native cotton, before the coming of the Spaniards, and wool after the arrival of their

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

sheep, furnished the materials for making blankets and garments for daily use, and ceremonial garments, kilts and sashes. The few colors used were those of the native wools and cotton, of natural dyes and imported indigo, until the advent, late in the 19th cent., of aniline dyes. The designs were and still are simple stripe patterns or borders with diamond, triangular and terraced motifs either woven in the fabric or added by brocading or embroidering with wool. See Ruth Bunzel, *The Pueblo Potter,* 1929; Mary-Russell F. Colton, *The Arts and Crafts of the Hopi Indians,* Museum of Northern Arizona *Museum Notes,* Vol. 11, No. 1, July, 1938; Denver Art Museum, Dept. of Indian Art, Bulletins: *The Hopi Indians,* Leaflet No. 13, 1930, *Hopi Indian Basketry,* Leaflet No. 17, 1931, *Hopi Indian Weaving,* Leaflet No. 18, 1931, *Hopi Indian Pottery,* Leaflet No. 47, May, 1932; Edward Kennard, *Hopi Kachinas,* 1938. —H.G.

**hora.** A folk-dance of disputed nationality. Most authorities include it among the dances of Roumania, but in the recent revival of Palestinian folk arts, it has emerged as a dance of Hebrew origin. It seems possible that Jewish people living in Roumania introduced the hora to Roumanian folk-culture. The dance as performed by Jewish people today is similar in many ways to the Roumanian version, but different in that the Jewish hora has a chanting accompaniment which is sung in Hebrew by the dancers. The Jewish hora is a gay and vigorous dance in 2/4 meter, usually performed in a close circle which symbolizes the unity of the group. The Roumanian hora has a slow introduction, during which the men dance alone while the women gradually approach the circle. Both dances are characterized by a gradual increase in speed and range of movement. —J.G.

**Horai** (Jap.). Buddhist land of eternal spring —paradise.

**horizon, horizon line.** See PERSPECTIVE.

**horizontal.** *Mus.* Term used figuratively to designate the succession of musical elements, particularly the progress of melodic lines.

**horizontal line.** See PERSPECTIVE.

**horn.** See MUSICAL INSTRUMENTS.

**hornacina** (literally, little oven). Niche in the corner of a Mexican 17th-18th cent. palace for the figure of the patron Virgin or Saint of the family, often placed above the main cornice in a raised and specially ornamented section of the parapet. —J.Mc.

**horned lions.** See SYMBOLISM IN FAR EASTERN ART.

**horror vacui.** See SYMBOLISM IN FAR EASTERN ART.

**horse hair, artificial.** A rayon product, made in imitation of the natural horse hair. It consists of single strands of any desired length, and in very heavy deniers, usually 300 to 450. It is made either round or flat. Its advantage over the natural horse hair is that it can be produced in optional lengths. Artificial horse hair behaves exactly the same as the viscose rayon yarn. Used for mats, ribbons, belts, millinery, braids, galloons and hats. —G.W.R.

**horseshoe arch.** See ISLAMIC ART.

**Hoshino yaki** (Jap.). Pottery made in Chikugo province.

**hoso-e** (Jap.). A vertical style of print about 12 x 6 in. in size.

**hossu** (Jap.). See fly-whisk.

**hourglass drum.** See MUSICAL INSTRUMENTS.

**hourglass motif.** In classical art, an ornament consisting of two triangles set one on top of the other, point to point; usually this unit is repeated continuously in a row. —L.T.S.

**hours, canonical.** The matins, lauds, prime, terce, sext, none, vespers and compline—portions of the day set aside by rule (canon) during which devotional services are prescribed such as singing of the psalms, hymns, etc. Of eastern origin, the canonical hours were adopted by monasteries and the Church itself in the early formative period. —V.A.

**house.** Structure of moderate size to shelter the group life of one single family group. A more or less strict segregation of the family group within the tribe occurs in all primitive societies, although collectivism may prevail in many activities. Apart from the clustered dwelling structures found with cliff and mesa dwellers and in certain timber construction as in North America, the use and construction of compartments for individual matrimonial and family units seems to have been one of the earliest customs.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Nomadic populations speedily erected temporary structures as homes, or where their migration habitually took them through areas, poor in handy structural material of any kind, as the drylands of Arabia, or the grasslands of the North American Middlewest, prefabricated, collapsible, transportable dwellings in form of tents were substituted. Like with tepees, the ownership of the home and its furnishings, esp. its floor covering, was often fixed with the wife, not the husband. In case of polygamy, each wife frequently produced, owned and maintained the mat on which to receive the husband, as well as the tent or abode in which these simple furnishings of daily life were placed. Reed constructions and entire adobe villages were structurally processed and often maintained by women in ritualistically repeated activities. The introduction of heavy materials, such as timber and rock, supplanted female by male labor in house construction; but in spite of the individual house, collective construction of each house in the community by cooperative effort of the village has subsisted in many regions from Yucatan to Slovakia.

The early house frequently is not merely a dwelling place but a place of production as far as such production of a pre-industrial economy depends on and requires indoor and controlled climate. Up to the recent time of the North American pioneer, spinning, weaving of textiles, making of pottery, of candles, of crude wood furniture, sewing of clothes and above all the processing of food stuffs, baking, pickling, salting of meat, preserving of fruit and a hundred other productional activities took place, required space and found architectural expression of some sort in layout and design of the house. Animal husbandry, the care of domesticated animals segregated itself but slowly from its concept, and chickens, rabbits, goats, cows shared long with dogs and cats the right of the master's and owner's roof. This type of peasant dwelling with lean-to's, and consequently a plan of picturesque accumulation and roof configuration, sentimentally influences to this day the idea of home, while the derivative and diminuations of the landowner's mansion and the nobleman's castle furnish other historico-psychological components. Pronounced protectiveness against intrusion and against the discomfort of climate and weather, a minimum of openings, heavy walls for insulation, fireplaces and expressive chimneys are in many ancient traditions identified with the idea of comfortable home, and the house of the forefathers. Cottages reminiscent of English and French peasants' cottages, Swiss chalets, Mexican ranch houses, Cape Cod fishermen's huts have in painfully variegated rows invaded the suburban subdivision of yesterday's metropolis.

The unprecedented increase of population, the great density of settlement in even very decentralized and fully motorized sectors of civilized countries, further the irreversible industrialization of practically all commodity production now placed apart and outside of the home. All these facts profoundly change the destiny of house design and home comfort. It is anomalous to expect that the requirements of a greatly modified usage, the very much changed aspirations of a new generation, and finally, the new and so different industrially processed materials, tools, construction methods would permit the maintenance or revival of historical design pattern for the contemporary house or the house of the near future. —R.J.N.

**household art.** (art ed.) A phase of art concerned with the selection, arrangement, furnishing, care, and maintenance of the home and of its immediate surroundings, often including a study of exterior and interior architecutre, landscape design, period styles of furniture and furnishings. Whitford and Winslow in *Dictionary of Education.*

**housing.** An expression and a concept relating social reform to conditions of shelter and habitation. Emphasis is hereby placed on needs of the masses of population.

Apart from a certain collectivism in the design or in the structural process in primitive villages (see domestic architecture; house) the housing of families, understood as a large scale socio-economic issue, has historically occurred in certain efforts of colonization, and similarly, in order to secure labor for a certain local manufacture (Fuggerei, 16th cent., Augsburgh, Germany), or to induce the migration of trained workers into a less civilized but not directly colonial region (Frederic II, settlements of skilled French weavers in Brandenburg, Germany, middle 18th cent.).

Housing as a remedy for consciously observed socio-economic deterioration, was first conceived in conjunction with other allied and general reform movements, such as those initiated by Robert Owen, Fourrier, Saint Simon; Marxism in its earlier stages did not pay programmatic attention to this particular phase of societal reconstruction. Up

to the conclusion of World War I, remedial criticism of housing conditions, and of the consequential significance of slums, remained largely in the hands of middle class and moralistic reform societies; but problems of sanitation esp., caused at least preventive legislation by states and municipalities, to curb boundless deterioration of living standards and the manifold threat of blighted dwelling areas to the community as a whole.

The garden city movement based on ideas and exemplary action of Ebenezer Howard and Raymond Unwin, originated in England, produced model housing for medium, but not for low incomes. It spread to Germany, Switzerland, Belgium, Holland, and influenced plans of consumer cooperatives in the Scandinavian countries.

After World War I, housing of the workers and the lowest income groups was recognized by Continental governments as in line with other public utilities, and as an object of administrational responsibility. The municipalities of Vienna, Frankfort, A. M. Amsterdam, Rotterdam, Berlin, et. al., during the 20's of this century, prided themselves on having rehoused between 10 and 20 per cent of their respective populations in model housing projects. A scattered *avant guard* of the architectural profession in Europe, North and South Africa, West and East Asia, concentrated attention on housing as a vital ingredient of city and community planning. (C. I. A. M.—Congres Internationaux D'Architecture Moderne).

The American countries, esp. the U. S. A. and Mexico, followed this worldwide movement since the economic depression of the 30's and housing of newly migrated defense workers speeded this activity for a brief period until the current material shortage interrupted most construction during the exhaustive efforts of World War II. Housing is recognized as a peace work reserve of staggering magnitude, to combat post-war economic depression and unemployment. Its significance in improving and stabilizing society can hardly be overestimated.

In contrast to post-Victorian subdivisions, the most advanced recent housing projects excel in an *extension and continuity of communal areas, uninterrupted* by *rolling traffic,* safely enjoyed by children and endowed with *community buildings, day nurseries, kindergartens* and *recreational facilities* for all age levels. The tendency is to produce a rather self-contained *restful neighborhood, in which coherent social activities may develop,* and the amorphous vasts and wastes of yesterday's urban life are avoided. variations of one of the Maya languages. This term is also applied to the culture found in that region which is fairly homogeneous, although subject to the variations implicit in development over a long period of time. —G.C.V.

**Hudson River school.** See POST-REVOLUTIONARY PAINTING AND SCULPTURE IN THE U. S. A.

**hue.** See COLOR.

**humanism, the new.** A philosophical and critical doctrine popular in the 1920's. Founded by Irving Babbitt and Paul Elmer More, this ethical interpretation of man's place in the universe gave precedence to human free will guided by intuition over theological or scientific determinism. Being the master of his own fate, man can direct his own progress; he must avoid extremes and follow the Aristotelian middle path in conduct and in art. Rousseauistic romanticism and materialistic naturalism became arch enemies to be destroyed, for the former cultivated unfettered individualism and the latter permitted an intellectual attitude of irresponsibility. Classical art and derivative principles were considered the upholders of established cultural values; emphasis was placed upon tradition to such an extent that critics considered the doctrine untenably aristocratic in a democratic society, as well as anti-scientific in an age of science. See N. Foerster, ed., *Humanism and America*, 1930; C. H. Grattan, ed., *The Critique of Humanism*, 1931. —H.R.W.

**hydraulis.** See MUSICAL INSTRUMENTS.

**hydria.** A Greek water pitcher. In the 6th cent. B.C., these vases were characterized by broad-bellied, egg shapes, sometimes with two stubby handles but usually with a large one at the back and two smaller ones at the sides. By the beginning of the 5th cent. B.C., Athenian potters refined the shape, slimming the body, flattening the shoulder, and uniting the neck and body with a graceful curve, thus making the hydria among the most attractive of Greek vases. —W.R.A.

**hydrologic cycle.** See CIVIC PLANNING.

**hymn.** According to St. Ambrose (c. 340-97) a hymn was a song in praise of God. Later hymns also honored the Virgin and Saints.

During his exile in Phrygia, Hilary of Poitiers (d. 366) became acquainted with Syrian hymnody. Upon his return to Gaul (c. 360) Hilary's attempt to introduce hymn singing failed because the Gauls apparently lacked artistic perception. Although Isadore of Seville (c. 570-636) refers to Hilary as the first Latin hymn-writer, to Ambrose goes the credit for introducing the hymn from the east into the services of the Western Church. Four hymn-texts with certainty can be ascribed to the Saint: *Aeterne rerum Conditor*; *Deus Creator omnium*; *Iam surgit hora tertia*; and *Veni Redemptor gentium*. It is impossible to say if the melodies associated with these texts were also written by Ambrose. They may well have been set to pre-existing melodies. Each hymn consists of eight four-line stanzas in iambic dimiter, and each stanza is set syllabically to the same melody. This simple structure was ideal for congregational singing in the antiphonal manner. Metrical hymns written in this form in the following centuries were known as *hymni Ambrosiani*. The famous *Te Deum* known throughout the Middle Ages as the *Hymnus Ambrosianus* is not by Ambrose as was formerly supposed but probably by Niceta of Remesiana (c. 335-414).

St. Benedict (c. 480-543) gave hymnody order and method which characterized the Western ritual of later times. The Rule of St. Benedict prescribed the regular singing of Ambrosian hymns in the Offices for the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

*Canonical Hours* (q. v.). Eventually hymns found their way into the Divine Service.

Among the hymn writers who followed Ambrose are Prudentius (348-c. 410), Sedulius (1st half 5th cent.), Gregory I (c. 540-604), and his friend Venantius Fortunatus (530-609). New meters were introduced from time to time but the Ambrosian model remained dominant. Also must be mentioned the Venerable Bede (c. 672-735) and Theodulph, Bishop of Orleans (d. 821) who wrote the celebrated hymn for Palm Sunday in hexameters and pentameters, *Gloria, laus, et honor tibi sit, Rex Christe Redemptor.* As in the case of Ambrose, the authorship of the melodies is uncertain. Many of these melodies are to be found in the *Antiphonale,* the *Vesperale* and the *Liber Usualis.*

With the "invention" of the *Sequence* (q.v.) by Notker (d. 912) a new era came into Latin hymnody. See Julian, J., *A Dictionary of Hymnology,* 1925. —V.A.

**i** (Ch.). Sacrificial bronze vessel. Two-handled with flaring rim, to hold sacrificial food. Sometimes rectangular with cover. *I* is also a generic term for all ritual bronze vessels. —J.A.M.

**I. C. I. standard observer, white light.** See COLOR.

**ichi-mai-e** (Jap.). A single-sheet woodblock print in black and white.

**iconoclasm.** The rejection of and active enmity against the use of images in religious cults; an attitude which is the antithesis not so much of the aesthetic and sensuous as of the magic approach towards art. Its argumentation therefore, usually either draws attention to the magic practices connected with image worship (medieval iconoclasm) or it accepts the presupposition of such practices by identifying images with the divinities they portray and then proceeding to decry them as inimical to a spiritual God (Hebrew iconoclasm). Underlying the contest between *iconoclasts* and **iconophiles** (the friends of images) is the problem whether man should try to reach God directly by shunning all sensuous blandishments of the world or whether he should penetrate to him through images and symbols. The term iconoclasm came to prominence first on occasion of the iconoclastic struggle, which from 725-842 A.D. divided the Byzantine world into the hostile camps of friends and enemies of images. In present terminology it is frequently used to designate any movement against established idols, material or spiritual. —R.B.

**iconoclasts, Byzantine.** The struggle against religious images in the Eastern Roman Empire which began between 724 and 726 and found its final end in 843, when the Feast of Orthodoxy was instituted to commemorate the victory of the upholders of religious imagery, was one of the great religious, political and cultural crises of Byzantine history. The emperors who initiated and chiefly encouraged iconoclasm were Leo III (717-41) and his son Constantine V (741-75), and then, after the iconophile interval of Irene's reign (780-802) and the temporary rehabilitation of the holy images by the second council of Nicaea in 787, again Leo V (813-20), Michael II (820-29) and Theophilus (829-42). The reasons for the outbreak of iconoclasm in the Byzantine Empire should not be sought merely in puritan and even less in rationalistic tendencies. Byzantine iconoclasm was an outgrowth and indeed the climax of the caesaropapistic theory and praxis of the State, as represented by some of the most successful emperors. The example of Jewish and Mohammedan hostility against images seems to have played a not unimportant role. Early-Christian anti-idolatrous tendencies were to some extent revived, but they alone do not suffice for an explanation of the struggle, as the destruction of religious images was accompanied by a remarkable increase of secular imperial imagery. It seems that the iconoclastic emperors understood the old idea of priestly rulership in such a way that only their sacred empire was to be the material form of Christendom in the world. Accordingly, the supra-natural sphere should remain as abstract as possible, and Christ and His saints should not be expressed visibly in images.

The iconclasts succeeded in destroying most of the pre-iconoclastic Christian imagery in the central regions of the Byzantine Empire. During the reign of Irene and after the ultimate victory of orthodoxy the upholders of the images destroyed practically everything

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

of iconoclastic church art which had been ornamental and symbolical. As a lasting consequence of iconoclasm, sculpture in the round disappeared completely from Byzantine art, while reliefs were allowed. There was never an official prohibition of statues in particular, but the esp. close association of statuary art with pagan idolatry as well as the oriental artistic trend which transformed plastic forms into pictorial patterns, led to this result.

—G.B.L.

**iconophile.** See iconoclasm.

**iconostasis.** See RELIGIOUS PAINTING IN RUSSIA.

**ictus.** See MEDIEVAL MUSIC.

**idealism.** Idealism grows out of the conception that all individual things, in so far as they belong to a certain genus, go back to an original, primeval image. This primeval image is the lasting essence through its changes of manifestation. It cannot be found in any individual form which can be perceived by the five senses. It is immaterial. For instance, behind all individual men who have been, who are, or who will be, there lies the idea of man. Imagine, perhaps all human forms photographed upon the same negative; all the qualities characterizing and distinguishing one single individual from another would become equalized and all qualities which men have in common would be emphasized. From the modern point of view, it could be called a "standardized" form, a standard necessarily arising from the manifold variety of individual figures. This idea, therefore, represents the primeval law, or the primeval image from which every separate figure is descended. In the same way that the idea of "mankind" exists, so the idea of "man", and of "woman" exists. There are as many ideas as there are general; e. g., the idea of animal, plant, tree, landscape, etc.

Since this primeval image is eternal and immutable, it must be calm and since this image realizes the primeval law, it must be self-sufficient. Consequently all powers contained in the image become equally, or even symetrically balanced. Since all opposed variations which characterize and distinguish the individuals are made equal, a primeval calm arises from it and causes the entire disappearance of all such variations; this means that all lines must be continuant and must be retraceable to their starting point. Since these qualities are to be found most perfect in a circle and in forms similar to a circle, idealistic art will express itself mainly in these forms.

The artist devoted to idealistic art should demonstrate the qualities of primeval images in his works; he stands in opposition, let us say, to the artist who is near the individualized or characteristic art. The difficulties of idealistic art lie in the fact that the artist should keep away, on the one hand from the single living individual, and on the other hand from some inanimate pattern, and he should combine that which fills with life the single being with the immutable law. The creators of idealistic art were the Greeks. The climax of this art occurred in the 5th and 4th cents. B.C. In Hellenistic and Roman times idealistic art continued with certain deviations characterizing the changed situation. During the development of Roman art the ideal conception became gradually so very changed by oriental and Germanic influences that in the medieval times following, art took its origin from a quite different point of view than in the antique world. In the 2d half of the 12th and the 1st half of the 13th cents. a distinct inclination toward ideal conceptions is to be noticed in European art. This we call the epoch of the proto-Renaissance.

The renewal of idealism upon a broader basis began in Italy during the 15th cent. This movement, called the Renaissance, invaded the whole of Europe from the South. But, because the point of origin of the post-medieval period was motion rather than calmness, the Renaissance was entirely unable to create and continue idealism. As this element of movement gradually became more and more pressing, the original idealism was forced to change into an overstressed idealism, which we call the baroque. This transition began with Michel Angelo. There is a renewal of idealism in the 18th, 19th and 20th cents., the so-called Classicism. —A.J.S.

**idiom.** *Mus.* Fundamental organization of musical materials, brought into evidence through the common practice of numerous composers during a considerable length of time and forming the assumptions from which the principles of composition applied in the period under consideration can be derived. The organization of the material constituting an idiom is manifest in choices of preference concerning particularly the **vocabulary** (selection of tones to be used); the character of the basic elements (e.g. intervals in melodic progressions and between simultaneously sounding tones; chords; rhythmic and metrical principles); the type of textural relationships (e.g. monophonic, polyphonic, homophonic; qq.v.) between the elements; the distinction between consonances and dissonances (qq.v.); the treatment of dissonances, etc. (The term **idiom** is also used to designate individual features peculiar of a style (q.v.); e.g. certain melodic figures are idiomatic in the Palestrina style, certain harmonic progressions are idiomatic with Wagner, certain rhythmic phenomena are idiomatic in Spanish folk-music, etc.) In the music of the Western civilization three chief idioms can be distinguished: modality, tonality, atonality.

A. **Modality** is the oldest of the three idioms. Its main principles are: (1) The vocabulary of modality is the seven tones of the diatonic series which has within each octave segment five whole-tone and two half-tone steps. (2) For systematical purposes, tones appearing in prominent places (mainly at phrase endings) of modal music are considered **key-notes** of different modal scales which thus are distinguished by the different locations of the whole-tone and half-tone steps in relation to that key-note which is called the ***finalis*** (**final**) of the mode. Definition and nomenclature of the modes have varied considerably from antiquity throughout the Middle Ages. The names given to the modes are derived from the terminology evolved by the theorists of ancient Greece. The following classification, formulated in the Renaissance period, accounts for most cases of modal music (*finales* in brackets after the name of the mode): Ionian (C), Dorian (D), Phrygian (E), Lydian (F), Mixolydian (G), Aeolian (A). These are the authentic modes. There is an equal number of **plagal**, or **hypo-modes**, so designated because their names are formed by adding the prefix *hypo* to the name of the corresponding authentic mode. The plagal modes have the same *finales* as the corresponding authentic modes. Roughly speaking, a melody is ascribed to an **authentic mode** when its lowest tone is identical with the final of the mode and the range of the melody covers approximately one octave above the final. A melody is ascribed to a plagal mode when its range reaches approximately four tones below and five tones above the final (e.g. a melody with final C and the range G-g is called hypo-Ionian, etc.). Thus the modes are a system useful for the classification of melodies according to what segments of the diatonic series they characteristically cover. (3) Alterations of the tones of the modes (modifications through raising or lowering tones by half-tone steps) are used sparingly and conditionally. On the basis of the diatonic series C-D-E-F-G-A-B, the following alterations were admitted almost exclusively: C sharp, E flat, F sharp, G sharp, B flat (not their enharmonic equivalents; see enharmony). (4) Early modal music was monophonic (see monophony) (e.g. Gregorian chant). Later (particularly ecclesiastical) modal music was polyphonic (see polyphony). Because of the prevailing contrapuntal texture (see counterpoint) of this music, the intervals formed between the various voices were of paramount relevance, and increasing attention was paid to their different degrees of tension (see consonance), until definite and consistent distinction was made between consonances and dissonances, the use of the latter being restricted by detailed regulations as to preparation, resolution, metrical placement, etc. In the course of this evolution, the allegiance of a melody to a particular mode became determined rather by the more and more typified approaches to the final (see cadence) than by the range covered by that melody. A beginning of harmonic orientation became manifest particularly in the behavior of several voices participating in cadences, so that in the latest period of modality homophonic texture gained increasing significance. (5) In modality, cadences on other steps than the final of the mode can have one of the following forms: [a] in the approach to the cadence tone, only tones of the original mode are used; [b] a cadence formula typical of the mode of which the cadence tone is the final is used; [c] the cadence tone is treated as the final of the original (or some other) mode transposed to a pitch level different from that of the original mode (e.g., a phrase in the Ionian mode may have an intermediate

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

cadence on A; in the case [a] the cadence tone A may be reached from G; in the case [b] it may be reached from G sharp which suggests a cadence formula typical of Aeolian; in the case [c] another voice may have C sharp (the major third of A, instead of the minor third, C, available in Ionian), which suggests that the tone A is considered the final of an Ionian mode beginning on A, in other words: that the phrase "modulates" to "Ionian in the key of A" (see key). The use of this modulatory principle was restricted to such processes which did not involve the introduction of other alterations than those listed under A.(3). (6) In ecclesiastical modal music, the relative metrical weight of melody tones is determined chiefly by rhythmic conditions (length; see rhythm) and location within the range of the melody (pitch). The various contrapuntal principles applied in different periods of modality presuppose an arrangement of the basic rhythmic units of the melodic lines in groups of two or three (double, or triple, time). This concept, however, does not imply a dynamic stress (see accent) on every first unit of such a group. Especially in ecclesiastical modal music, points of emphasis appear in the various voices at irregular time intervals. In secular modal music a tendency towards coincidence of the points of emphasis with the first units of the basic rhythmic groups is manifest.

B. **Tonality** is the idiom which superseded modality in the later part of the 16th cent. As far as the vocabulary was concerned, the transition from modality to tonality consisted mainly in that two of the Renaissance modes, Ionian and Aeolian, were used preferentially, later exclusively, under the name of major and minor modes. Intermediate cadences on other steps than the *finales* of these two modes were regularly treated according to the process described under A.(5)[c], so that each step of the two basic modes could be considered the final of a transposition of one of the basic modes. In the late 17th cent., especially under the assumption of the Equal Temperament (q.v.), this concept was made applicable to each of the twelve tones available within the range of an octave. On account of these evolutionary processes, tonality can be considered a specific case of modality. Since, however, the transition from modality to tonality implied essential changes of fundamental principles of composition, it is advisable to reserve the term modality for the idiom described under A. The principles of tonality, as compared to those of modality, are the following: (1) Tonal music is characterized by prevailingly harmonic orientation, even in cases of contrapuntal texture (e.g. J. S. Bach). Therefore the tones of the tonal scales have significance above all by virtue of the functions ascribed to the chords built in intervals of thirds upon the degrees of the major and minor scales (triads, seventh chords, etc.), the functions being a set of principles by which chord progressions are evaluated aesthetically mainly with respect to the position of the roots of the chords in the scale and to the intervals between the roots of consecutive chords. In order to classify the functions, the tones of the scales are given the following names (in ascending order): Tonic, Supertonic, Mediant, Subdominant, Dominant, Submediant, Leading Tone. (2) Each tone of the twelve tones available within the range of an octave can be made the reference point for identical sets of harmonic functions. In other words, each of the twelve tones is the key-note of a major and a minor scale. Thus the major and minor modes appear each in twelve different keys. The keys are given names after their key-notes (e.g.: C major, C minor, C sharp major, C sharp minor, etc.). (3) The concept of **modulation**, viz. transition from one key to another by interpreting elements common to both keys as having functions in the key to be left as well as in the key to be introduced, is used without the restrictions attached to it in modality (see A. (5) ) and became one of the most effective devices of articulation of form in tonal music (see articulation). (4) Tones not belonging to the scale of the basic key were used with increasing frequency, as tonality developed. Such tones are considered alterations of, or substitutions for, tones of the basic scales, and as such they affect the harmonic functions in various characteristic ways. The five tones available in each key for such purposes are called **chromatic tones.** More recently the term "chromatic" is used for any melodic progression in half-tone steps. (5) In the course of evolution, distinction between consonances and dissonances, from the outset overshadowed by the principle of harmonic functions, became gradually less relevant. (6) The basic groupings of rhythmic units, similar to those of modality (double, triple time, or composites of these like six-eighth, five-four, etc.), have metrical significance in that

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

musical elements placed on the first units of such groups (bars) carry accents (see accent). Phrase accents by which articulation in spans larger than the basic rhythmic units is secured may, or may not, coincide with the accented rhythmic units. Symmetry (q.v.)—recurrence of metrical situations in regular time intervals—is characteristic of tonality. The evaluation of chord progressions laid down in the system of harmonic functions is brought into close reference to the rhythmic and metrical conditions of tonal music. (The term **tonality** is sometimes used to designate the existence of any kind of relationships between musical sounds, necessary to make their presentation aesthetically meaningful. In this sense, tonality is a synonym of music. If the term is so used, the three idioms discussed here appear as different forms of tonality. In this case it would be necessary to apply another term at least to the idiom described under B., in order to discuss the differences between the three idioms. Hence it seems advisable to use the terms tonality only in the sense outlined under B.)

C. **Atonality**, in a purely linguistic sense, is any idiom characterized by the absence of the properties of tonality, as outlined under B. (Thus, modality might be considered a case of atonality.) The term atonality is more specifically used to designate the idiom which evolved from the tonal idiom in the 20th cent. In the latest period of tonality, the increasingly frequent use of chromatic tones obscured the harmonic functions and the principles related to them to such an extent that they could not any longer be relied upon for the derivation of the principles of composition applied in a large portion of contemporary music. Although it is possible to identify any isolated musical element as belonging to one, or more, of the keys of tonality, many of the contexts in which elements were placed in the 20th cent. suggest the formation of a basic organization different from that of tonality. The main principles of atonality, as compared to those of the other idioms, may be outlined as follows: (1) The vocabulary of atonality is the twelve tones available within the range of an octave. They are used without reference to a normative selection, or selections of tones (modes) from that vocabulary. (2) Factors of reference (tones, chords, motifs, etc.) emerge through the relative emphases put on them in their particular contexts rather than from a generally binding system of relationships (such as the harmonic functions of tonality, the cadence formulae of modality, etc.). Melodic, rhythmic, harmonic (in this order) correspondences between different parts of a structure are the principal factors in establishing unity of design and articulation of form. (3) Polyphonic orientation prevails in atonality. Therefore, and because of the absence of a harmonic reference system, the degrees of tension of intervals between the various voices are of a relevance similar to that which they had in modality. Consonant combinations, however, are used rather sparingly. (4) Increase and decrease of tension are also the criteria according to which chord progressions are mainly evaluated wherever atonal music has a more homophonic texture. Factors modifying and specifying the amount of tension which a chord has by virtue of its constituent intervals (see Chord) are location of those intervals in relation to each other, dynamic conditions, sound color (timbre), **voice leading** (character of the motion by which the different voices, especially the top and bottom voices, reach the chord), rhythmic and metrical situation. (5) Chords may be built on any of the twelve tones and be constituted by any kind and number of intervals. (6) Rhythmic and metrical conditions of atonal music, especially of the polyphonic type, resemble to a considerable extent those of modality, although the systematical accent (dynamic stress on the first unit of a basic rhythmic group; see Accent) still plays a more or less important part. Phrase accents are distributed prevailingly in irregular time intervals. —E.K.

**Idolino.** A bronze statue in Florence, representing a graceful standing youth. It has many of the characteristics of Polyclitus' sculpture, especially the wavy pattern of the hair and the serence pose of the body and facial expression. —W.R.A.

**Iga yaki** (Jap.). Pottery made in the province of Iga.

**Igeta yaki** (Jap.). Pottery made in Tanba province.

**ihia** (Jap.). Ancestral tablet. A small lacquered tablet on which the name of a deceased ancestor is inscribed. These ancestral tablets are hung in the family shrine. —J.A.M.

**ikake-ji** (Jap.). A lacquer technique in which the entire ground is covered with gold.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**ikat** (Jav.). A type of weaving whereby, before being woven, yarn is dyed by the tie-dye method to synchronize with the pattern desired. —J.A.M.

**ikebana** (Jap.). The art of flower arrangement. See *Japanese Flower Arrangement,* Mary Averill, 1928; *The Art of Flower Arrangement in Japan,* A. L. Sadler, 1933; *Japanese Flower Arrangement for Modern Homes,* Margaret Preininger, 1936; *The Art of Japanese Flower Arrangement,* Alfred Koahn, 1934.

**illuminating.** *Book.* Ornamentation in gold and colors, usually on vellum.

**illumination.** See BOOK ILLUSTRATION; PSYCHOLOGY OF ART.

**illusionism.** The effort in painting or sculpture to create as nearly as possible an illusion of visual reality. The painting or modelling of "substitute objects", i.e. objects so like their prototypes as to serve in the manner of substitutes for them. Naturalism (q.v.) and impressionism (q.v.) are forms of illusionism. Perspective, foreshortening, chiaroscuro for the sake of modelling form or defining transient effects of light striking a surface, representational line drawing, and microscopic and *trompe l'oeil* detail are all potentially aids to illusionism, which is more essentially an applied science than an art and can be taught by academic rules and demonstrations. Photographs and casts from the live model may be used by illusionistic painters and sculptors as crutches to aid in achieving their ends. In sculpture the material used is made to imitate real flesh or drapery; painting of the figure in natural colors may be employed; real hair or clothing may be added; a base may be omitted so that under ideal conditions the spectator may indeed be led to an erroneous perception and believe himself actually in the presence of the original imitated by the sculptor.

In practice few artists have coveted pure illusionism at any time in history, but in the late 19th cent. and in the Hellenistic period they came nearest to it. The term "illusionistic" is used comparatively, however, to describe West Christian art as opposed to East Christian, the Odyssey Landscapes as opposed to Greek art of the 5th and 4th centuries B.C., *quattrocento* (q.v.) Italian art as compared with medieval Byzantine or Gothic, Renaissance art in comparison with contemporary, Western art in contrast to Oriental. —L.D.L.

**image sequence.** See PHOTOGRAPHY.

**imagination.** The faculty of having images, i.e., sensuous mental concepts; or, in a less restricted sense, the faculty of building up any kind of mental concept; with an emphasis on the power of evoking these images or concepts in the absence of the real objects represented by them. As expressing the power of free evocation, unfettered by adherence to factuality, the word describes an important aspect of artistic creativeness. In modern aesthetic discussions, the term usually has for its background the idealistic philosophy of Kant and his followers, of F. W. J. Schelling, S. T. Coleridge, R. W. Emerson, and others. These thinkers viewed art as the product and manifestation of human creativity. "Imagination" (*Einbildungskraft*), adopted as a name for the faculty of artistic conception, was considered by them an effluence of the creative center of human personality. Coleridge defined imagination as "the living Power and Prime Agent of all human Perception" (*Biographia Literaria,* Ch. XIII), and also as the "soul" of poetic genius (*Ibid.,* Ch. XIV). He distinguished it as an animating and integrating power from "fancy", the "drapery" of genius, which "has no other counters to play with, but fixities and definites." Much in the same sense a later author, Bernard Bosanquet, asserted that imagination is not a separate faculty but "the mind at work" (*Three Lectures on Aesthetic,* 1915, p. 26). —H.K.

**imagism.** A poetic movement which flourished in Eng. and U. S. from 1909 to 1917. T. E. Hulme's esthetic philosophy stirred Ezra Pound to unite a group hostile to romanticism and friendly to the innovations of modern French poets, to the recently translated Chinese and Japanese epigrammatic verse, and to Greek and Roman classical poetry. Chief members were Hilda Doolittle, Richard Aldington, and John Gould Fletcher. After editing *Des Imagistes* (1914), Pound withdrew, and Amy Lowell assumed active leadership by asking that the group subscribe for three years to a fixed program. Their credo, announced in *Some Imagist Poets* (1915), included the use of exact words from common speech in condensed and suggestive expression, the avoidance of clichés, the creation of new rhythms to express new moods, the free choice of subjects from modern life,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

and the presentation of concrete, firm, precise pictures or images (hence the name). They wrote chiefly in free verse (q.v.) forms. See Glenn Hughes, *Imagism and the Imagists,* 1931. —H.R.W.

**Imarki yaki** (Jap.). Japanese pottery made in Hizen province.

**imitation.** *Mus.* Device of polyphonic composition by which a melodic phrase, or motif, presented in one part is repeated shortly afterwards in another part while the first part continues with a suitable counterpart. **Imitation by inversion** is imitative repetition of a given melody using its inversion (q.v.). —E.K.

**imitations of old masters.** See FORGERIES IN PAINTING.

**impasto.** Used to describe the mixture of pigment and medium (oil or turpentine, or both) with which a picture is painted.

**impost.** The top member of a pillar, pier, wall, etc., upon which the weight of an arch rests.

**impregnation method.** See RESTORATION OF PAINTINGS.

**impresa.** Any pictorial emblem when used as the insignia of a person (or group of persons) provided that it refers through metaphorical implication either to the life story or to the aims, beliefs and convictions of that person. In absence of such metaphorical implication any impresa will degenerate into a mere mark of cognition or heraldic sign. Although often no more than a piece of fashionable pedantry the impresa was originally and primarily meant to be a tool for the training of the will designed to remind its "owner" by its ubiquity in his environment of his permanent ideals and aspirations. —R.B.

**impression.** See PRINTS AND PRINT PROCESSES.

**impressionism.** A variety of naturalism (q.v.) which depicts objectively the world of ephemeral appearance. (1) The effort to present a general impression of an incident, a view, or an object, rather than to record it in detail, to paint or model what the eye sees at a glance, not what it knows to be there,—accomplished ordinarily with comparative rapidity and suggesting a sketch of the bare essentials. Ideally the doctrine requires an objective attitude with no personal comment, no alteration or exaggeration of the record of instantaneous vision for the sake of design or personal self-expression, as in the case of expressionism (q.v.); but this ideal is seldom completely realized in practice either in painting and sculpture or in poetry and prose. Normally the attention of the artist is concentrated upon superficial appearances, as opposed to inner structure of forms or events, which distinguishes impressionism from abstraction (q.v.). The human meaning or underlying essence of forms or events is programmatically neglected by the impressionist, who therefore has nothing in common with realists, idealists, and romanticists (q.v.). Like all formal naturalists he restricts his interests to the world of vision, but some impressionists are also philosophical naturalists, i.e. naturalists in content as well as form.

Used in the broadest sense the term impressionist includes such artists as Frans Hals, late Velasquez, some Hogarths (e.g. the *Shrimp Girl*), the antique painter of the *Odyssey Landscapes,* Turner, some Constables, Whistler, Sargent, Liebermann, Sorolla, Rodin, et al., as well as the French artists of the late nineteenth century to whom the term applies in a special sense.

(2) Specifically impressionism implies the study of light reflecting on surfaces as exemplified in the work of Monet, Pissarro, Sisley, et al., in late 19th century French painting. These artists made a scientific study of light and color, and have sometimes been called "luminists" to distinguish them from impressionists in the broader meaning of the term. They used the "pointillist" or "divisionist" method of applying paint in small spots of pure color (i.e. color not previously mixed on the palette), and by this method succeeded in getting the bright tones of sunlight. They painted rapidly in the open rather than in the studio and, foresaking composition and design, form and inner structure, interpretation and subject interest, recorded short-hand impressions of light striking on the surfaces of the same objects at varying times of day and under varying atmospheric conditions. For the most part they painted landscapes.

They were first called impressionists after an exhibition held in Paris in 1874. Some of the other artists who exhibited with the impressionists at the various group shows of the 1870's, when impressionism was the latest movemen in art, were at most transient impressionists, or else were never consistent be-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

lievers in the doctrine in the "luminist" sense just described, or were more interested in capturing fleeting movement than fugitive light effects. Such was the case with Cézanne, Degas, Renoir, and Gauguin. Other impressionists of the late 19th and early 20th century include Bazille, Guillaumin, the late Manet, Berthe Morisot, and such Americans as Mary Cassatt, Sargent, Childe Hassam, Twachtman, Weir and Friesecke.

(3) As applied to sculpture, impressionism refers to modelling of forms with bosses and hollows, which do not describe form with anatomical accuracy or reveal the essential structure of form, but which reflect light in such a way as to create the illusion of natural form; and it further refers to modelling which captures the sense of fleeting movement. Impressionism in sculpture developed later and was influenced by the movement in painting, and is more pictorial than plastic. Hence impressionist sculptors are exclusively modellers rather than carvers and their natural media are bronze and terra cotta. Rodin is the chief representative of impressionistic sculpture, but the sculpture of Degas and some of the modelled works of Carpeaux, Barye, Epstein, George Gray Barnard, and Gutzon Borglum, are also impressionistic.

(4) As applied to literature, impressionism is an endeavor uncritically to express the immediate, hyperesthetic, vibrant sensations produced by the external world. It involves an intensely nervous style of picturesque virtuosity and is little concerned with formal clarity. Its pictorialism shows the influence of impressionist painting of the day. In literature, more often than in painting, subjective attitudes creep into impressionism. The Goncourt brothers represent impressionistic literature in purest form. Later writers like Pierre Loti and the Symbolist poets use impressionistic methods, but in order to attain more subjective and expressionistic ends. In America impressionistic form is used by Ezra Pound, Carl Sandberg, Amy Lowell, Sherwood Anderson, and John Dos Passos, but without a consistent objectivity.

(5) Applied to music, impressionism is sometimes used to describe the work of such men as Debussy and Ravel, and is used in general, whatever the date, in referring to descriptive music based on pictorial subjects, but, as in literature, subjective qualities and formal order are stronger in impressionistic music than in analogous painting. —L.D.L.

**impressionistic criticism.** See art criticism.

**impromptu.** *Mus.* Extempore; an improvisation; a piece in the manner of a fantasia.

**in** (Jap.). See seal.

**Inbe yaki** (Jap.). Pottery made in Bizen province.

**Inca art.** See ABORIGINAL AMERICAN ART.

**incandescent bodies.** See COLOR.

**incense burner.** See koro.

**inchoate.** Lack of organization with specific reference to the treatment of the emotional aspects of a literary work. The word indicates that the emotional responses recorded in the work have been inadequately felt, reflected upon, and analyzed. Hence, the work does not tell with any accuracy or finesse what the emotional effect was: it can only say that it was strong or 'overwhelming'. The inchoate work of art is bad because it exhibits an inability to bring order and clarity into one's feelings. —I.J.

**India rugs.** Introduced into India by the Mohammedans in the beginning of the 11th cent. The Emperor Akbar introduced Persian workmen about end of 16th cent. Followed Persian design at first. Two types of patterns: (1) Field divided into quatrefoils or ogee compartments each containing a naturalistic plant or floral forms. (2) Detached sprigs of flowers arranged in various ways. —B.E.J.

**INDIAN ART.** Art in India, since its beginnings, has been dedicated to the great religious systems of India: Brahmanism or Hinduism, Buddhism, Jainism, and the many indigenous nature cults that have always flourished in southwestern Asia. It has been an art concerned with the statement of the traditional principles embodied in these faiths and never with the self-conscious creation of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

beauty for its own sake. The monuments of the great periods of Indian art history are icons with the primary utilitarian function of presenting the divine prototype in material form for the express veneration of the worshipper. If they are beautiful or moving, it is because they have been effectively fashioned to fulfill this purpose and not because the craftsman deliberately set out to make something "artistic" with superficially pleasing surfaces. It was the final purpose of art in India to present to the believer all of the truths and certainties of his religion.

*The Indus Valley Culture* (*c. 3300-c. 2000 B.C.*). The earliest known examples of art in India are the material fragments of a great civilization that flourished in the Indus valley from 3300 to ca. 2000 B.C. Little is known of the people who built up the great commercial city of Mohenjo Daro, but it can be definitely established that this culture antedated the invasion of the Aryans in the 2nd millenium B.C. From the finding of objects of Indian manufacture in the ruins of Tell Asmar and other centers of early Babylonian culture it has been determined that commercial and artistic links related the civilizations of the Indus and the Two Rivers. It is for this reason that the name "Indo-Sumerian" has sometimes been used to describe the culture of Mohenjo Daro. The designation of "Indus Valley Culture" is, however, to be considered more appropriate for a period so predominantly Indian in character. The few fragments of sculpture found at Mohenjo Daro include a number of male heads and busts faintly suggestive of Mesopotamian forms in their conventions and heavy, static form which may perhaps be identified as priests of a Shamanistic cult. A small male torso, discovered at Harappa (Pañjāb), is completely Indian and, in certain respects, already prophesies the expression and technique typical of the historical periods of Indian art; it is distinguished by that miraculous realization of the very quality of flesh in stone that has always been one of the special achievements of the Indian craftsman. The surface of the skin is taut, as though undergoing the tension of an expanding inner force. It is this quality that is responsible for suggesting the roundness and fullness of the form. This is a technique of elimination in which all details of superficial imitation are avoided and only the essential articulation and form of the body are given. By far the most numerous class of objects found at Mohenjo Daro are the small steatite seals or talismen with remarkably living carvings of such typically Indian animals as the zebu, the urus ox, and the elephant in addition to representations of divinities both Indian and Mesopotamian. The animals are represented from the conceptual point of view in that each element of the anatomy is shown from its most characteristic aspect; and the creatures appear marvellously imbued with life.

*The Maurya Period* (*322-185 B.C.*). With the final disaster that overwhelmed Mohenjo Daro it was as if a shroud had been drawn over Indian art history for more than a thousand years. No authenticated objects of art can be assigned to that epic period from 1500 to 400 B.C. which saw the compilation of the Vedic hymns and Brahmanas, the rise of Buddhism and Jainism, and the emergence of modern Hinduism. Indian art, indeed, seemingly only emerged from the darkness with the rise of the Maurya dynasty and the creation of a new tradition of monumental art, possibly under Western influence as a result of the invasion of Alexander the Great (327 B.C.). Now, for the first time, we find a new art, dedicated to the propagandizing of the religion of Buddha. The forms of this art are in all likelihood of Iranian and Greek derivation, but its symbolism is explicitly Indian. Generally associated with that great patron of Buddhism, the Emperor Aśoka (272-232 B.C.), are the tall columns or lats, many of them over fifty feet in height, which were erected at the sites sacred to the omission of Buddha both in India and in Nepal. The most famous and beautiful of these monuments is the pillar that once stood at Sārnāth, scene of the Buddha's first preaching. It was surmounted by a capital consisting of four lions upholding a gigantic wheel. Although it is possible that this memorial was raised as a solar symbol prior to the time of Aśoka, it came to be regarded as emblematic of the universal domination of the Buddha's Law, typified by the great Wheel or *dharmacakra*. The lions, which formed a throne for the wheel, are reminiscent of the style of Achaemenid Iran; the four smaller animals, carved on the plinth, might have been done by workmen imported from the Hellenistic regions with which the Mauryan emperors maintained diplomatic contacts. If the art of the Mauryan column is properly speaking a royal art wrought largely by foreign craftsmen, forms of a more popular and Indian character are represented by the many colossal statutes of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

*yaksas* and *yaksis* dating from this same period. These figures, as an example of which one may select the Parkham *yaksa* in the Muttra Museum, are the earliest examples of monumental figure sculpture in stone. They are characterized by an absolute frontality and an almost overwhelming weight and massiveness. It is almost certain that they represent the first attempt of sculptors long accustomed to working in wood or metal to translate the techniques of these media into stone. It must be remembered that these statues of nature spirits, like all later Indian icons, are not conceived as possible biological organisms based on an observation of human models, but rather as symbols of great simplicity and power in which only those features essential to expressing the protective and generative faculties of these beings is presented to the worshipper.

*The Sunga and Early Āndhra Periods (c. 200-25 B.C.).* If the sculptured figures decorating the Buddhist monuments of the Sunga and Early Āndhra periods, such as the *yaksīs* on the Buddhist railing at Bharhut, seem to mark an improvement over the seemingly archaic conceptions of the Maurya craftsmen, this is not to be interpreted as a sudden turning to the observation of nature, but rather as the more direct and more effective realization of mental images and their projection into material form by craftsmen who were now completely conversant with the technique of stone carving. In this as in all other periods of Inlian art the Indian artist was guided by a system of prescribed canons and proportions to which he accommodated the object of his making, the object with which he identified himself in yoga meditation. The sculpture of the Sunga period consists mainly of the reliefs decorating the Buddhist railings surrounding the stupa at Bhārhut and the enclosure of the sacred precinct at Bodh Gayā. Some of the *yaksī* figures reveal a poignantly direct sense of the full beauty of the human form, conceived not as an articulate or possible biological organism but as the totality of so many individually beautiful and mechanistically joined parts. Here for the first time we may see developing the iconography of the Buddha story. In this period of Indian art He who had passed into the realm of invisibility where neither gods nor men shall know Him was represented only by symbols, such as the Wheel and the **Bodhi Tree**, emblematic of the great events in His earthly mission. The carvings of this period are concerned with directness of communication; laws of normal vision and all such considerations as perspective and spatial arrangement are of little importance for the representation of these events of no time and no place which exist as eternal certainties in the heart and mind of the worshipper. Among these Buddhist primitives one may select as especially magnificent embodiments of the Indian ideal the decorations of the four gateways of the stupa at Sāñchī, erected in the Early Āndhra period (c. 72-25 B.C.). No more eloquent and expressive embodiment of the sensuality and desirability of the feminine form exist anywhere in the art of the world than the *yaksīs* which swing like living vines from the *toranas* of the sacred enclosure. The parts of the body are simplified and emphasized with the clarity of poetic metaphor. Never is there the least suggestion of the imitation of the accidental or actual form of any human model, but rather the presentation of the essential or permanent structure beneath the surface appearance of things. The narrative panels at Sāñchī, very deeply carved so as to gain full advantage of the brilliant Indian sunlight, show us a number of consecutive incidents shuffled together without regard to chronological associations almost in the same way that these images are stored all together in the mind of the artist.

Something must be said about the **stupas** or relic mounds, of which the sculpture discussed above provided the principal decoration. These in their simplest form were hemispherical tumuli on a square or round base and surmounted by a superstructure consisting of a balcony-like member or *harmikā* and a mast supporting a number of parasols. It seems that originally such mounds were raised for royal sepulchral type was used to enshrine the relics of the Buddha and His saints. In addition to its function of enclosing the corporeal remains of the Tathâgata and as a symbol of His *Nirvāna,* the tumulus embodied in its architecture the Indian concept of the world. The base represented the earth; the hemispherical cupola, the enclosing dome of the sky; and the umbrellas, the various heavens or planes of reference that rise one above the other on the world axis above the finite realm of man. The dome of the stupa figuratively encloses the shape of the world mountain Meru, on the summit of which is set the heaven of the Thirty-three Gods, architecturally represented by the *harmikā.* This symbolism is thoroughly compatible with Bud-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

dhist doctrine in that the Buddha had come to be regarded as equivalent to the world itself; the stupa is that world; it is the architectural body of the Buddha miraculously animated by the quickening presence of the relics.

Also dating from the Sunga period are a number of rock cut sanctuaries or *caitya* halls, notably the shrines at Bhājā, Bedsa, and Kārli in the immediate vicinity of Bombay. These Buddhist cathedrals are basilican in form with a rounded apse usually containing a carved stupa as the principal object of worship. The body of the grotto temples is divided into nave and side aisles by rows of columns terminating in the ambulatory. It is believed that all of these elements including the rounded vault and the façade in the shape of the *pipal* leaf are imitations in stone of pre-existing free-standing temples of wood and thatch. The exact symbolism of these impressive cave-temples is not known, but it is believed that, like the stupa, they are reconstructions of the fabric of the cosmic house. The earliest rock cut shrine in India is the Lomas Rsi cave dating from Maurya times; the Bhājā temple has been dated about 200 B.C.; and the largest of these monuments at Kārlī was dedicated in 80 B.C.

*Greco-Buddhist Art* (*1st-6th cents. A.D.*). It seems strangely paradoxical that one of the schools of art most important for the whole future development of art in India and all Asia is not properly Indian at all but largely the creation of foreign craftsmen: this is the so-called Greco-Buddhist school of sculpture that flourished in Gandhāra (northwestern India and Afghanistan) from the 1st to the 6th cents. A.D. It has been assumed without really suffiicient evidence that the hypothetical existence of a school of Hellenistic art in Bactria was directly responsible for the development of the debased Classic style in Asia; however, from the date of the monuments and from their style it is apparent that Gandhāra sculpture is simply the easternmost florescence of Late Antique art (q.v.) and might indeed be regarded as a provincial Roman school created with the participation of artisans imported to these regions from Syria or some other province of the eastern Roman empire with which the sovereigns of Gandhāra are known to have maintained an intimate commercial relationship. The Gandhāra sculptures were largely the donations of that foreign dynasty of kings, the Kushanas, of Scythian stock, who were masters of all northwestern India and Afghanistan in the period under discussion. The Gandhāra sculptures are, of course, Indian in content in so far as their subject matter is entirely Buddhist, but their style is marked by that same abstraction of the humanistic Classical formula found in late Roman and Early Christian art. The principal contribution of the school to Asiatic art was its creation of the Buddha image. The Great Teacher is represented with the features of a Greek Apollo and in the pose and costume of a Greek philosopher. Only in the very last phases of its existence did the Gandhāra school produce sculpture of a marked esthetic character. The images in lime plaster that decorated the monasteries of Hadda in southern Afghanistan are marked by a sort of spiritualized realism that seems to prophesy the achievements of Gothic art in the 13th cent. Especially significant for their influence on Chinese Buddhist art are the two colossal Buddhas, 120 and 175 feet in height, that were hewn from the sandstone cliffs at Bāmiyān in the 5th and 6th cents. A.D.

Architecture in Gandhāra is represented chiefly by the ruins of monastic establishments in the environs of Taxila and Peshawar. The plan of these buildings is very simple, consisting of a number of courts with cells for the monks' habitation and niches for the images. The stupas of northwestern India and Afghanistan are more elaborate than the earlier types, and in their original state were clothed in a revetment of Buddhist statuary in lime plaster and stone.

*The Kushan Period* (*c. 50-320 A.D.*). Exactly contemporary with the hybrid productions of the Gandhāra school is the sculpture that once ornamented the sanctuaries of the southern capital of the Kushan kings at Muttra (Mathurā). Some scholars believe that the artists of the Kushan school and not the foreign workmen in Gandhāra were the first to represent the Buddha in an anthropomorphic shape. The Buddha statues from Muttra, some of which date from the reign of King Kanishka (128-160 A.D.), are thoroughly Indian in their form and expression. They have the heroic proportions of the *yaksas* of the Maurya period. The magic marks or *laksana* and other attributes calculated to express the superhuman proportions of the Buddha are all explicitly portrayed. The most famous of these is the statue dedicated by the monk Bala at Sārnāth in the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

third year of Kanishka. It is distinguished by that same remarkable suggestion of the warmth and softness of the flesh already described in works of earlier periods. The figure has none of the effeminate beauty of the Apollonian Buddhas of the Gandhāra school but is conceived in completely Indian terms. No less Indian in their overblown voluptuousness are the extremely sensuous carvings of *yaksīs* that ornamented the enclosures of the stupas at Muttra. A unique type of sculpture at Muttra is to be found in the portraits of the Kushan monarchs. These absolutely rigid and frontal effigies of Kanishka and other princes of the dynasty have little that is Indian about them and seem more nearly related to the statues of the royal portraits of Parthia.

It seems likely that the famous Mahābodhi temple at Bodh Gayā, although considerably modified by restorations in the Pāla period (730-1197 A.D.) and an almost complete reconstruction in the 19th century, was built as early as the 2d cent. A.D. Its form is that of a towering truncated pyramid flanked by four lesser towers raised on a podium-like foundation storey. Originally, the exterior was decorated with multiple Buddha images set in niches. The most interesting architectural feature of this building was unfortunately eliminated during the restorations of the 19th cent. This consisted of structural pointed arches and vaults in the inner chamber. This was an architectural element so thoroughly un-Indian that we are forced to conclude that it was introduced either from Iran or from the eastern Roman empire.

*The Later Āndhra Period (150-300 A.D.).* The art of South India in these same centuries is represented by the luxuriant and exquisite limestone sculptures from the great stupa at Amarāvatī, dedicated under the patronage of the kings and queens of the Later Āndhra dynasty. The svelte and languorous beauty of the figures that crowd the reliefs of the Buddha legend are at once a continuation of the canons of perfection of the Kushan school and a prophecy of the culmination of the Indian esthetic ideal in the work of the Gupta period.

*The Gupta Period: Painting (320-600 A.D.).* The Gupta period is one of the great epochs in Indian civilization, an exquisite and talented civilization, marked at once by the unparalleled magnificence and dusty splendor of the imperial courts and a flowering of all the arts—painting, sculpture, literature, and music. The most perfect expression of the luxurious and sophisticated elegance of this Golden Age is to be found in the great cycle of wall-paintings that cover the walls of the rock cut Buddhist sanctuaries at Ajantā. These wall-paintings are not illustrations of that primitive Buddhism reflected in the art of the Gardhāra and Kushan periods, but are dedicated to that developed form of the religion, the Buddhism of the Great Vehicle or Mahāyāna. Predominant are the princely forms of the ***Bodhisattvas,*** at once saving deities and incarnations of the Buddha's virtues, who throng the pantheon of this now thoroughly mystical and esoteric faith. One of the great masterpieces of Indian art is the Bodhisattva of the Blue Lotus in the first of the twenty-six caves at Ajantā. The figure looms as a mystic vision of divine loveliness and compassion before the ecstatic eyes of the humans and animals that fill the giant composition. The figure is not modelled on any standards of beauty, but is composed in a canon of proportion and ideal shapes calculated the more effectively and appropriately to evoke the divine and superhuman nature of the Great Being. Just as the poet employs the metaphor to suggest the beauty of his subject, so the Indian artist employs shapes drawn from the animal and plant world to describe the final perfection of the godly anatomy; as is specifically indicated in the manuals of artistic practice, the eyes are in the shape of lotus petals; the tensile curve of the Indian bow describes the arched loveliness of the brows; leonine is the sinuous torso; the truly flower-like hands suggest the orderly beauty of the growth of lotus blossoms. Certainly, the languorous ease of gesture and pose in this as in all the Ajantā figures is based on that language of gesture that was so vital a part of the Indian dance and drama. The compositions of the Ajantā paintings are not clear and symmetrical, but are densely crowded arrangements of figures and setting in which there is a continuous stirring and movement from figure to figure and group to group that provides a kind of rhythmic internal unity. These paintings, although Buddhist in subject matter, seem to affirm an almost lyric devotion to the beauty and warmth of the world of the senses. They are marked by that dualism of spirituality and sensuality that in a sense is not a dualism at all, so united are these opposites here as in all Indian art.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

*The Gupta Period*: *Sculpture.* The Buddha images of the Gupta period are the final realization of the Indian aesthetic ideal in the cult image. The humanistic Gandhāra Buddha, so inappropriate as an object of worship because of the distracting element of naturalism, has been replaced by an image completely Indian in conception. These images carved at Muttra in the 4th and 5th cents. A. D. are a combination of traits and techniques developing out of the Gandhāra and Kushan schools: the contribution of the Gandhāra style is the anthropomorphic conception of the Buddha, the technique of representing the drapery in string-like folds, and the carving of the face in simplified, sharply cut planes; the Kushan school has contributed the heroic proportions of the superman and the typically Indian technique of suggesting the warmth and softness of the flesh. In the sandstone images excavated at Sārnāth all reminiscences of Greco-Roman techniques have fallen away, and not even the slightest indication of folds interrupts the smooth, abstract surfaces of the bodies revealed in garments whose presence is shown only by the borders. These figures are composed in accordance with pre-conceived canons of mathematical proportion. The features and the body are built up in the same metaphorical language as the forms at Ajantā. A fixed vocabulary of gestures or *mudrās* (q.v.) determined the position of the hands. The statues have a crystalline harmony of abstraction, the final perfection of the religious diagram so often used in place of icons in the religious art of the East. Images like the famous Buddha in *dharmacakra mudrā* at Sārnāth are the last and fullest embodiment of the serenity and spiritual power of the Thathâgata manifested in material form. Another master work of this period is the torso of the Bodhisattva Avalokiteśvara from Sāñchī in the Indian Museum, London. The numerous steles from Sārnāth with reliefs of the Buddha show a translation into Indian terms of the iconography developed in the school of Gandhāra.

*The Gupta Period*: *Architecture.* In the Gupta period there emerges a type of temple which, in its essential elements, provides the arrangement of sanctuaries for all later periods. In such temples as No. 17 at Sāñchī and the 6th cent. shrines at Aihole a cella-like sanctuary or *garbha gṛha* is preceded by one or more pillared porches. The shrine proper is surmounted by a conical spire or *śikkhara.* The final development of this type may be seen in the medieval temples of Orissa, consisting of a towering *śikkhara* and a number of terraced porch-pavilions or *mandapa.*

*The Medieval Period*: *Sculpture.* (*The chronology of the Mediaeval period is generally given as* 600-850 *A.D. for Early Mediaeval, and* 850-1200 *A.D. for late Mediaeval*: *actually the date of the latter period may be extended to the 19th cent. to include such phenomena as Cola art and Rajput painting.*) The art of the Mediaeval period is almost entirely Hindu in content. As early as the 6th cent. Buddhism, permeated by doctrines of a magic and secret nature, entered the period of its final decline that culminated in its extinction or re-absorption into Hinduism. The last school of Indian Buddhist art flourished under the Pāla and Sena dynasties which ruled in the Bengal valley from the 8th to the 12th cents. In style this sculpture is a rather dry and mannered continuation of Gupta techniques. The chief importance of this school is that it furnished the canons for all the later centuries of Buddhist art in Tibet and Nepal. At the same time that great Buddhist teachers were imported into Tibet from Nālandā and other Indian centers by Sron Tsan Gampo, artisans from these places found their way over the Himālayas as well. The earliest monument (8th cent. A.D.) heralding the revival of Hinduism is the great relief of the Descent of the Ganges at Māmallapuram. This was a dedication of the Pallava dynasty that had succeeded the Āndhras in eastern and southern India. This relief covers the face of an enormous boulder on the sea-shore south of Madras. In it are represented life-size figures of elephants, deer, monkeys, and all manner of creatures human and divine gathered to give thanks for the miraculous descent of the sacred stream from Heaven. The animal forms, although not direct copies from nature, reveal such a wonderful sense of the articulation and movements specific to each of these species that they seem almost to be endowed with an actual life of their own. This seeming naturalism reserved for the members of the animal kingdom is in direct contrast to the abstract canons in which the figures of the celestial beings are conceived. Although much more attenuated and even lighter than the figures of the Gupta period, the forms of the *devas* are really a prolongation of the proportions and standards of beauty of the Golden Age.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

The figures are portrayed in such radically simplified planes that they both suggest the glyptic nature of their material and are magnificent embodiments of sculptural form.

The most notable single sculpture at the famous site of Ellura is the deep, grotto-like relief in the Kailāsanātha temple depicting Siva's subjugation of the demon Ravana. This composition, which is one of a number drawn from the legend of the *Rāmayana,* is so deeply carved that the figures appear in the full round in a box-like stage, and the most violent effects of light and shade are thereby achieved to enhance the dramatic emotion of the scene. The attitudes of the principal figures are all calculated to stress the fear and tension of this moment when Ravana threatens to uproot the sacred mountain. In their svelte attenuation and dynamic movement the forms are a continuation of the Pallava style of eastern India.

Stone sculpture in the Later Medieval period seems to represent a kind of drying-up and almost mechanical reproduction of the great style of the 8th cent. With few exceptions the images encrusting the later temples of eastern and southern India are only parts of a decorative symbolical scheme and hardly worthy of individual esthetic consideration.

The greatest artistic achievements of Hindu art in the Medieval period are in the South Indian metal images of Saivite gods and saints. Most notable among these are the many representations of Śiva as Lord of the Dance that embody in plastic form the flux and vibration of the god's endless destruction and re-creation of the universe. The statues of Śiva saints in their suggestion of an inner quality of vibrant and ecstatic adoration are almost symbols of devotion itself.

*The Medieval Period: Architecture.* Hindu architecture of the Medieval period is sometimes rather conveniently divided into the Northern and Southern styles, although probably no such geographical division is really tenable. Distinctive of the northern type is the so-called *Śikkhara,* represented principally by the temples at Bhuvaneśvar in Orissa. The *Śikkhara,* rather like a bee-hive in shape, is constructed in clearly defined courses of masonry, emphasized by lotiform quoins or *amalakas* which, since the temple is a cosmic diagram, typify a hierarchy of deities or powers in the Hindu pantheon. Sanctuaries in the shape of stepped pyramids covered with numerous *stūpikās* are sometimes believed to be especially characteristic of southern or Dravidian India.

To this category belong two of the seven small sanctuaries at Māmallapuram: these, the so-called Seven Pagodas, are not true architecture, but rather sculptural replicas of free standing structures in wood and thatch. Another example of this type is one of the greatest monuments of Indian art: the Kailāsanātha temple at Ellura. This vast Saivite sanctuary whose architectural shape represents the form of the sacred mountain, Mount Kailāsā, together with the many porches, free standing columns, and vast sculptural decoration was directly hewn from a great quarry of rock. It was carved under the Calukya dynasty (650-750 A.D.). The dominant shrine is in the shape of a terraced pyramid, dominated by a bulbous member or *stūpikā,* the shape of which is repeated in smaller scale on the tiers of this terraced stupa structure.

*The Medieval Period: Painting.* No account of medieval art in India would be complete without at least a mention of the schools of Rājput painting that flourished in Rājputāna, Bunkelkhand, and the Pañjāb Himālayas from the 16th to the 19th cent. The universal subject matter of these exquisite pictures is Hindu epic legends; most often repeated of *Krsna-lila* legends is the refrain of Krsna's love for Radha in all its passionate beauty. The themes are expressed in terms of a stylized and linear loveliness; the lyric grandeur of the compositions harks back to the wall-paintings of the classic period. The colors have the translucency of stained glass. Rājput painting is medieval in its idiom and totally different from the Mughal school's preoccupation with realistic effects and the happenings of the contemporary world.

*Art in Ceylon.* The island of Ceylon was converted to Buddhism by Mahinda, the missionary-son of the Emperor Aśoka, in the 3d cent. B.C. Unlike India, Ceylon has remained a stronghold of Buddhism ever since. The earliest center of Buddhist art was the capital at Anurādhapura where a number of the giant *dāgabas* or stupas and other dedications of the early Buddhist kings may still be seen in the jungle. The sculpture found at this site appears to be derived from the Later Āndhra style of eastern India. Most of these remains date from the 2d to the 5th cents. A.D. In the succeeding period of confusion the Tamil invasions from southern India forced the removal of the capital to Polonnarūva. This was the last important

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

center of Singhalese culture in the 12th and 13th cents. The Buddhist art of Polonnarūva reveals the unchanged persistence of the forms of the early period. There have also been found at Polonnarūva copper images of Hindu deities which, although based on the canons of Medieval South Indian art, are superior in their refinement to their continental prototypes. Ceylon is not lacking in examples of the painter's art: the series of *apsaras* painted at Sīgirya in the 6th cent. A.D. are the vigorous local equivalent of the Gupta style. The very much ruined cycle of paintings at Polonnarūva is related to the painting of South India in the Medieval period.

It must not be supposed from the above that the art of Ceylon is completely without originality. The Buddha statues of Anurādhapura show a grandeur of conception that in its expression of the self-contained serenity of the master surpasses the Indian models.

*Art in Indo-China.* The introduction of the Indian art and religions into Indo-China and Siam follows a pattern somewhat similar to that presented by the art history of Ceylon. The earliest Buddhist and Hindu sculpture of the so-called pre-Khmer period (5th-7th cents. A.D.) reveals a more or less faithful transcription of Gupta prototypes, although a few masterpieces like the Hari Hara of the Phnom Penh Museum display a sculptural perfection surpassed in Asiatic art. What may be recognized as a definite Khmer formula manifests itself in the sculpture of the Classic period (8th-13th cents. A.D.), represented chiefly by the carvings decorating the temples of the capital at Angkor. There we see the developed Cambodian formula for the expression of the Buddha nature. The inner radiance of the deity is expressed largely through the eyes closed in reverie and the oft-repeated long slow smile of the lips. From the fact that the kings of Cambodia even in their lifetime were worshipped as earthly personnifications of the Buddha or one of the Hindu gods it is apparent that something like a recording of personal traits is frequently included in the abstract framework determining the representation of these cult statues of the god-king. The greatest monuments of Khmer architecture are the temples of Angkor Vat and the Bayon, built in the 12th and 13th cents. resp. The shrine of Angkor Vat represents the final development of Khmer architecture: in it the isolated towers which were the sanctuaries of earlier centuries are joined by galleries on several levels. Only the most primitive corbelled type of vault is employed in the Cambodian buildings and the stories are laid without mortar of any kind. Angkor Vat is at once the temple and the tomb of the *devaraja Suryavarman* II (1112-1152 A.D.), whose image in the guise of Śiva was enshrined in the topmost tower of the structure. Allegories of the king's earthly triumphs are contained in the reliefs from the Indian epics that cover the walls of the first gallery. The many smaller towers that echo the shape of the central spire are believed to have immortalized the great generals of the realm. The temple of the Bayon which stood in the center of Jayavarman VII's (1181-1201 A. D.) capital at Angkir Thom is another vastly complicated structure, dominated by multiple towers that have on each of their four sides carved faces of the Bodhisattva Lokeśvara. This is intended to indicate the spread of the royal power to all points of the compass. The statue of the god-king in this temple was a Buddha seated on a Nāga. The temple of the Bayon in conjunction with the walls and moat of the capital was a magic reconstruction in architecture of the world structure with Mount Meru at the center surrounded by ramparts of mountains and the great ocean encompassing all. The sculpture of the Bayon represents a softer and more subtle development from the sculpture of the Classic period, just as its architecture is the final and most complicated evolution from earlier and more simple types.

*Art in Java.* One of the great centers of Indian colonial art was the island of Java where, under the powerful dynasty of the Śailendras (ca. 750-860 A.D.), Mahāyāna Buddhism produced its noblest monument in the great sanctuary of Barabudur. This structure has the hemispherical profile of a giant stupa enclosing a stepped pyramid or ***prāsāda.*** The ancient symbolism of the sky-dome enclosing Mount Meru is easily recognizable in these two architectural elements; in fact, Barabudur is the most complicated illustration of the principle of ***pratibimba*** whereby the cosmos is magically reconstructed in architecture. The temple is more than this; it is a magic diagram or ***maṇḍala*** of the material and spiritual worlds comprehended within the mind of the Universal Buddha. The subjects of the reliefs of the successive galleries lead the pilgrim upward through the worlds of desire and form to the final contemplation of the world without form and action symbolized in the seventy-three stupa-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

enclosed statues of Vairocana Buddha. The allegory of the monument is brought to completion by the statues of the Buddhas of the Four Directions that fill the niches on the four façades of the building. The style of the reliefs of the galleries, as though confirming the hierarchy of their subject matter, progresses from a direct and naturalistic treatment of the subjects from the world of desire to a very abstract and spiritualized presentation of the realms of the mystic Buddhas that adorn the uppermost corridor. The Buddha statues are the final crystalline perfection of the technique and canons of proportions of the Gupta period. See Anand, M. **Indian lake.** See lac.

**Indian red.** The name of this pigment originally indicated a natural iron oxide imported from India. It was slightly different from most other varieties of red earth in having a somewhat purple tinge. Now the name is used for any pigment that has such a color, even for one that is artificially made by calcining copperas. The words, **rouge,** as used in industry for a polishing material, **colcothar,** and ***caput mortuum,*** all stand for this same pigment. —G.L.S.

**Indian yellow.** As an artist's pigment, this was always rather rare and is now practically out of use. It was formerly prepared in Bengal and was a dried extract from the urine of cows that had been fed on mango leaves. Its color is deep, translucent yellow-orange. For an organic pigment, it is fairly stable, even to light, is slightly soluble in water, and is decomposed by hydrochloric acid. A synthetic substitute is now often sold under the same name. —G.L.S.

**Indianist literature.** See HISPANIC AMERICAN LITERATURE.

**Indigo.** Probably the oldest of the organic blue colors, indigo is strictly a dye. It is yielded by different plants of the *Indigofera,* and has been grown all over the world but particularly in India and China. Bengal indigo was considered one of the best grades and was widely used as a dye for fabrics. Unlike most of the organic colors used as a painter's pigment, this was not precipitated on a base but was ground to a fine powder as a dye and thus mixed with different mediums. Synthetic dyes have largely displaced it but it is still used to a limited extent as a water color. In an aqueous medium it is more satisfactory than in oil and is moderately stable when well bound and covered with a varnish film. —G.L.S.

**industrial art.** (1) Art of the machine in which manufacture and, usually, production is sought; (2) (as distinguished from *industrial arts*) art as applied to industry. Comp. w. *industrial arts*. Whitford and Winslow in *Dictionary of Education*.

**industrial arts.** (1) Broadly, an area of the school curriculum, or a field of study, concerned with the materials, processes, and products of modern industry; intended to familiarize pupils with the industrial elements of modern civilization vocations, and to provide opportunities to acquire skill in the use of tools and materials in the construction of useful objects; (2) more narrowly, a term used in preference to the older designation, *manual training*. Dist f. *industrial art*. Whitford and Winslow in *Dictionary of Education*.

**industrial art school.** A school that specializes in the training of students for employment as artists in the industries. (Such artists are often called *stylists* or *industrial designers*.) Whitford and Winslow in *Dictionary of Education*.

**industrial design.** Structural or three-dimensional design of objects for industrial mass production by machine tools, e.g. radios, clocks, light fixtures, electric irons, automobiles. Contrasts with two-dimensional design for commercial advertising or decoration, and with pictorial design in the fine arts of painting and sculpture. —L.D.L.

**industrial music.** Music over plant communication systems to industrial workers; now provided by several hundred plants in the U. S. A. and most of those in the British Isles. —W.A.K.

**industrial music library.** A collection of current and standard phonograph records used for broadcast over plant communication systems to industrial workers. One firm (RCA) supplies a factory with an initial library and then provides for a monthly exchange service so that the library may be kept up to date. —W.A.K.

**INDUSTRIAL MUSIC RESEARCH.** Secretary of Labor James J. Davis stated in 1922 that "We have come to realize that there is a big field for music in the industrial and commercial world". Before the end of that decade, music was being broadcast to some American workers over industrial sound systems. Consensus at that time, according to Clark (2), was that music played while employees worked had a beneficial effect on morale, fatigue, and earnings. Anecdotal evidence favorable to music has been so positive that relatively few serious attempts at controlled scientific evaluation of music's effects have been made. It is now realized that this is a vitally important research field for socio-industrial psychology.

Industrial music research is primarily concerned with the determination of the influence of recorded music as broadcast over factory communication systems upon workers' efficiency, aesthetic appreciation, attitudes, feelings of pleasantness and tiredness, and general morale. It is apparent of course, that this research also faces the task of evaluating the effect of myriad *kinds* of music upon the same important factors. Current opinion on operation of industrial sound systems holds that "hot swing" and certain other types of music are not good from the standpoint of factory production. There is no agreement as yet as to types of music most valuable at various periods in the work spell.

Quantitative reports of effect of music on industrial output are meager but consistent. The classical study to date is that reported by the British Industrial Health Research Board (17) in 1938; in this study Wyatt and Langdon found that over a period of 24 weeks during which twelve employees doing repetitive-type work experienced periods of no music and several kinds of music, daily production was increased 2.6 per cent by the application of music. Relative effectiveness of types on output (not conclusive because of small number of workers in experiment) are reported in the following order: one steps, fox-trots, waltzes, light classics. Their study of 350 other factory workers revealed that these employees feel that time drags worst during the first two hours of each half of the work-day, and that from 77 to 97 per cent of these same workers feel that they *can* think of other things while they work and that time passes more quickly when they *do* think of other things. The significance of this last sentence is considerable in the light of their further finding in an experiment with 19 employees in which those reporting boredoom did significantly less work than those not bored. Music's apparent favorable influence upon output is partly due to its ability to "take up the slack" in the mind of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

the worker which may be dulled by the constant concentration upon a repetitive task long since mastered.

In an experiment performed by Humes (5) at a Hygrade Sylvania tube factory, it was found that quality of work done by 88 female operators was significantly higher on the average (as indicated by scrappage data) during music than during no-music weeks. The last no-music week was interrupted by an employee petition demanding that the recorded music broadcasts be restored.

Less certain is the favorable effect of music on those less repetitive operations which require considerable continued mental concentration. Jensen (6) in a school experiment found that typing output was somewhat reduced by jazz and dirge music; of course he used perhaps the two worst types of music for stimulating output; it is possible that he might have obtained different and favorable results had he applied familiar sweet popular music or soft background music. As a matter of fact, the dirge music reduced speed but improved accuracy.

In a series of carefully controlled experiments, Hevner (4) has shown that for certain compositions, major modality, fast tempo, high pitch, flowing rhythm, and simple harmony tend to express happiness best. Unfortunately it is not yet known whether music with the best effect on worker output is the same kind of music which has best effects on the worker's morale and feelings of well-being, although there is strong indication that almost *any* pleasant kind of occasional music has more favorable effect on both production and morale than does no music.

Podolsky (11) has compiled facts which show that music tends in general to increase pulse rate, respiration, and metabolism, lower the threshold for sensory stimuli of different modes, and reduce the regularity of respiration. These conditions are certainly not characteristic of the organism when in a state of boredom.

In addition to the as yet meager scientific evidence, there is much published opinion to substantiate the partly experimentally confirmed thesis that music has several desirable influences in industry. Ramsay and Rawson (12) report from a 1939 British survey that 74.5 per cent of employers using music believe that it increases work efficiency. Wynford Reynolds (13), in charge of a British program, has declared of industrial music—"It is a tonic like a cup of tea, something to cheer the mind. You will get increase output all right, but it will be spread over the work-spell as a whole. You will not necessarily get it while the music is actually being played." Reynolds advises use of not more than 2½ hours of music a day, in periods lasting from fifteen to twenty minutes.

According to the British Industrial Welfare Society (13), "On the whole the concensus . . . seems to be that music at work does much to relieve the monotony of repetitive work, and produces a stimulus to increased output, and in the opinion of the Industrial Welfare Society there is no doubt that this development is not merely a wartime one, but that music at work will remain a definite feature of industry." As just indicated the British are making extensive use of industrial music and a recent headline dated from Switzerland, "Arms Output Slows So Nazis Try Music," indicates that it is also being adopted on the continent. Use of industrial sound systems is rapidly spreading in America as is shown by the fact that representative factories throughout the nation have made installations and by the additional fact that the largest sound manufacturer, RCA Mfg. Co., Inc., has a separate service for such industrial sound systems.

There are many categories into which music may be divided, although Peters (10), summarizing a review of aesthetic studies, observes that "It is highly significant that these studies . . . should find only two types and that all experiments of both kinds should identify the two corresponding *sets* in terms suggestive of form and meaning." Convenient practical terms for categorizing music for industrial research purposes include cultural type, tempo, familiarity, instrumentation, vocalization, styling, seriousness, volume variability, and recording level.

There is much opinion but few experimental results on effects of types of music. Mr. Wynford Reynolds maintains that British experience indicates that slow waltzes, rhumbas, hot music, music that is too thickly scored, and vocals should be avoided; much American experience challenges this ban on vocals. A survey of British employers using music showed that two-thirds of those reporting want vocals occasionally and a majority prefer men vocalists; fourteen types of broadcast programs received this rank order: light orchestra without vocal, ballroom orchestra without vocal, brass band without vocal, swing orchestra or accordion without vocal, small novelty combination featuring xylophone, band with five vocals, light orchestra dance band without vo-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

cal, theatre organ, rhythmic records of light classical music, dance-time records, military band, salon orchestra, dance band, band playing folk songs and dances of another nation.

Thorpe(15) studied the type preferences of 475 college and high school students after they heard an orchestra play eight types and found that the top four fell into approximately this order: military march, semi-symphony, concert waltz, descriptive piece (*Whispering Flowers*); type preferences were not notably related with intelligence, college grade, or curriculum pursued. Fay and Middleton(3) played four types of classical and two types of popular music over a sound system to 54 college students and the students ranked the types from most to least pleasant in this order: light classical, old classical, romantic classical, swing, modern classical, and sweet; all were rated as more pleasant than unpleasant. Women rated all types of classical higher than did men. Freyman(13) reports that analysis of 190 replies received from 250 British workers indicates a demand for more modern popular tunes, music-hall songs, dance-time music and waltzes and less light classical, marches, and hot jazz. All of these 190 replied that they consider music a pleasant background to their work.

Humes(5) concluded from an experiment in a tube factory that quality of output is generally better under all fast music or all slow music than under programs arranged with pieces proceeding from most to least familiar.

After experiencing several months of music, Wyatt and Langdon's(17) British factory subjects gave all their votes to fox trots and waltzes and none to one-steps, marches, or light classical. One-steps, however, appeared to have the most favorable effect on output.

Since gratification of felt needs tends to raise morale, it may be expected that providing music for employees will help morale; in a survey by Kerr(7) of 132 applicants in one U. S. Employment Office, it was found that a significantly larger number would rather work on a floor with music than on one without music and that such attitude tends to be negatively correlated with age. These findings may imply that in a scarce labor market, an employer with music may have the advantages of more and younger applicants to select from. Humes in a tube factory and foremen in many other plants have found that when broadcast music ceases for a few days for any cause, employees frequently protest and request its resumption. The fact, as shown by Wiebe(16), that frequent repetition of an unfamiliar song will tend to make it more popular tends to indicate that industrial music might be capable of raising average employee appreciation for semi-classical and classical music. In a study of 457 college students, Rigg(14) found that mere repetition increased appreciation and also found that almost any comment, even if unfavorable, increased appreciation. Fay and Middleton(3) conclude from one study that "For individuals who are sufficiently gifted . . . frequent exposure to the good may lead to a preference for the good." These studies strongly indicate that use of industrial sound systems should have considerable value in raising both employee's morale and level of appreciation for good music.

Tests to be used in measuring employees' preference for representative songs and types of music may be obtained from the Personnel Research Department of the RCA Mfg. Co., Inc., Indianapolis. For small scale experimental studies of program and music popularity, the Program Analyzer used by Peterman and Lazarsfeld(9) is a highly refined measuring instrument. This latter device makes it possible for a listener to record like or dislike for any part of a song or program by squeezing an appropriate button. A more useful instrument for general survey purposes is the *Attitudes Toward Music* scale developed by RCA Mfg. Co. to determine music type preferences of employees in order that plant broadcast programs will have optimum "fit" for the plant's personnel.

In an article on recent advances in human engineering, Kirkpatrick(8) observes that "The instinct with which the repetitive work of modern industry is said to come into conflict most seriously and most frequently is that of workmanship, or creativity. . . . He may experience . . . a pronounced feeling of boredom —an overwhelming tiredness that is not the result of actual physical fatigue, but an expression of monotony." Relief of this psychological fatigue is believed by many to be the greatest single value of music in industry. Theoretically the music may provide an element of creative expression which is absent from the work—or, as Cantril and Allport(1) point out, "Familiarity means progress toward mastery, and so long as the progress is *under way* the sense of enjoyment is retained. Perfect aesthetic mastery . . . is easily achieved in the case of popular music, at which time its appeal diminishes." REF. (1) Cantril, Hadley & Allport, G. W. *The Psychology of Radio,* 1935. **infra-red ray photograph.** Photograph made on plates or films especially sensitive to the long wave length in the infra-red end of the spectrum. A special filter is used on the camera. —H.M.

**infulae.** See tiara, papal.

**ingrain carpets.** Known as Kidderminster or Scotch carpet, is a flat weave and is usually made in a two-ply fabric with the aid of a "double cloth jacquard" machine. The term "two-ply" fabric in this case means two sets of weft yarns interchanged in such a way that while the pattern is alike on both sides the colors are reversed and can be used on either side. —B.E.J.

**initial.** An initial is the large letter at the beginning of a text, section, or paragraph. The word comes from *litera initialis,* from which the noun *litera,* letter, has been dropped; the adjective has taken over the meaning of the whole phrase.

The Romans had already stressed the beginning letter, as can be proved by the oldest extant manuscripts of Vergil dating from the 4th cent. A.D. These initial letters were enlarged in about twice the size of the other letters. They were enlarged in order to call attention to the beginning of a new section. The oriental people began decorating this initial letter. But only the people of the Celtic-Germanic cultural family gave the greatest importance to it, esp. in the Bible where one single letter or a compound of some letters covered an entire page and were decorated in a greatly enriched and costly manner. The oldest of these big ornamented letters appear in the Irish Evangeliar, the so-called Book of Kells, now in the Trinity College Library at Dublin. The Anglo-Saxons and the Frankish Merovingians also cultivated this art. The initial letter was taken over by the schools of Carolingian culture, and became the vogue for many centuries. In recent times the custom of emphasizing initial letters has been revived to a certain extent. See Lamprecht, *Initialornamentik des 8. bis 13. **ink.** The modern ink for writing is some kind of dye, the more traditional being the so-called iron gall ink. This is made from tannin or gallotannic acid derived from oak galls and combined with ferrous sulphate. The combination alone has no color but turns black when exposed to the air. These iron gall inks were probably taken up at some time in the early Middle Ages. In common use then and earlier was the carbon ink like that still prevalent in the Far East, made usually from finely ground lamp black with a weak medium of glue. The ink stick of China and Japan is of such composition and a similar mixture known to scribes and painters by the name, ink, was a common preparation in Europe during the Middle Ages and the Renaissance. —G.L.S.

**ink-painting.** See CHINESE ARTS.

**inlaid.** *Book.* An inlaid design in leather bindings in one having leather of another color or style inset into the leather cover.

**inner dance.** See form (3).

**In Nomine.** Was a composition based on a given melody sounded in long tones in one voice while the other parts interwove polyphonic and frequently imitative passages around it. The name of the form was derived from the text associated with the given melody which was most frequently employed (*Benedictus qui venit in nomine Domini*) though other subjects were also used. Even the **fantasia** on one note might fairly be included here, though the repetition of a single tone in one part undoubtedly reduces the concept of a given melody to its lowest possible terms. The form, though conservative in tendency and, in fact, an offshoot of the old Netherlands cantus firmus technique, was long practiced with interesting results by English composers. John Taverner appears to have been a pioneer in this form of composition. The roster of composers of In Nomines is a long one, and the form was much practiced during the latter part of the 16th cent. and the first decade of the following century. The works of Henry Purcell appearing after a long silence close the history of the form (c. 1680).

The delight of English composers in exhausting the possibilities of a single subject was not confined to the In Nomine. The *Miserere* was similarly employed as was an old folk theme, *The leaves be greene* or *browning.* Perhaps a unique record of a friendly contest in this kind of composition must have been contained in the *Medulla Musicke.* "Sucked out of the sappe of Two of the most famous Musitians that ever were in this Land, namely Master William Byrd . . . and Master Alfonso Ferabosco . . . either of whom having made 40tie severall waies . . . showing most rare and intricate skill in 2 partes in one upon the playne songe 'Miserere' ". This volume has, however, been lost. Like the **fancy** (q.v.), the In Nomine was predominantly intended for performance on the viols though examples in the Mulliner Organ Book and elsewhere are for keyboard instruments. —C.W.H.

**inro** (Jap.). A small receptacle which was suspended by a cord from the belt and in which pellets were kept. Generally divided into five compartments synchronized one over the other. See also netsuke and ojime, standard accompaniments of the *inro;* also "Catalogue of Japanese Lacquer, Part II, *Inro*", Victoria and Albert Museum, London, Edward F. Strange, 1925. —J.A.M.

**insert.** *Book.* Usually applied to a circular or leaflet placed loose between the leaves of a book.

**inside margins.** *Book.* Of two kinds: (1) The narrow border of leather turned in over the board of the cover leaving the margin around three sides of the pasted down end paper. (2) The white at the back center of the opened book between the two print pages. Also known as the **gutter margin.** —H.E.S.

**inso** (Jap.). See mūdra.

**inspiration.** Inspiration is well defined by Webster as "A supernatural divine influence which qualifies men to receive and communicate divine truth." The word itself implies the inward breathing of an informing spirit. In this sense, "All that is true, by whomsoever it has been said, is from the Sanctus Spiritus" (St. Ambrose on I Cor. 12.3). The Synteresis as "conscience" is the principle equally of prudence and art (cf. Renz, O., *Die Synteresis nach dem Hl. Thomas von Aquin,* 1911, p. 172; St. Augustine, *Conf.* XI. 5 *ingenium,* whence our word "ingenious"). Thus Meister Eckhart rightly speaks of the artificer as "inspired by his art."

It is in this way that "inspiration" has always been understood. Thus Hesiod, "The Muses breathed into (*enépneusan*) me a divine voice, and bade me sing" (*Theogony,*

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

31); Homer, "The Genius breathed into (*enépneuse*) my heart to weave" (*Odyssey,* XIX. 138); "It is the God himself that speaks . . . the makers are but his exponents" (Plato, *Ion,* 534, 535); "I do nothing of myself, but as my Father taught me, I speak" (John, VIII. 28) "I am one, who when Love (*amor,* the divine Eros, Apollo, Sanctus Spiritus) inspires me (*me spira*), attend, and go setting it forth in such wise as He dictates within me" (*Purgatorio,* XXIII. 53, 54, cf. *Paradiso* I. 19). The artist who can claim to have been inspired is one who does his work in accordance with "the pattern of all that he had by the spirit" (I. Cor. 28,12).

Inspiration pertains to the artificer's contemplative *actus primus* in which he "sees" or "hears", i.e. "imagines" the shape of the work to be done. The revealed scriptures of India are, accordingly, spoken of as "audition" (*śruti*); the sacrificers, when at a loss how to proceed with the construction of the Fire-altar are told to "reflect" (*cit*). Incidentally, the word "reflect" itself is significant of the essential of what is always an "imitation" (Platonic *mímetis,* Skr. *anukaraṇa*). There are many Indian stories of artists who ascend to inspect what Hebr. IX. 23 calls "the patterns of things in the heavens," and having taken note of them, copy their forms in the physical material here below; so that "it is in imitation of the divine works of art that any work of art is accomplished here" (*Aitareya Brāhmaṇa* VII. 27); "the crafts such as building and carpentry . . . take their principles from that realm and from the thinking there . . . such arts as are the offspring of intellect (*nous*) must be there" (Plotinus, *Enneads,* V. 9,11, 12).

The term "inspiration" has thus had always a precise meaning. The term is nowadays frequently misused by art critics who do not realize that the word "inspire" cannot be used in connection with effects produced on the artist by concrete objects external to himself. Thus we are told the female nude was Maillol's "exclusive inspiration" (*Parnassus,* May 1941); that the modern artist derives his inspiration from the very physical materials he works with" (Greenberg in the *Nation,* April 19, 1941); and that "the poet or artist may let the rain inspire him" (Rose, *Greek Mythology,* 2nd ed., 1933, p. 11). In all these cases the authors are using the word "inspire" when they mean "stimulate". The modern critic, if a rationalist, may deny the possibility of inspiration; but in this case he must never speak of an artist as having been "inspired"; for the word is excluded, by his own assumption, from his vocabulary. —A.K.C.

**instrumental anthem.** See anthem.

**instrumental vibrato.** See vibrato.

**instrumentation (orchestration).** The practice of adapting music for a group of different instruments; to arrange for an orchestra.

**instruments, musical.** See MUSICAL INSTRUMENTS.

**intaglio.** See aquatint; engraving; GLASS AND GLASS-MAKING; PRINTS AND PRINT PROCESSES; relief sculpture.

**intarsia.** Decorative designs produced by inlaying wood in a background of wood; much practiced in Renaissance Italy.

**integrated art program.** See art program, integrated.

**integration.** (Art ed.). (1) Promoting unified personality by making art contribute its share to experience as a whole; (2) making art in the school contribute its share to the curriculum as a whole. See *art program, integrated.* Whitford and Winslow in *Dictionary of Education.*

**intensified seeing.** See PHOTOGRAPHY.

**intensity.** (1) This term is used in two quite different senses in literary criticism. In one of these it is synonymous with *passion,* and indicates that the work issues from a vivid partiality and conveys the strong and spontaneous convictions of the artist. In another sense, intensity is a criterion of the artist's perceptual and intellectual acumen. Here, it indicates that a work exhibits careful attention to detail, and is a subtle and refined exploration of its subject-matter. (2) *Mus.* See NOTATION. —I.J.

**intensity and timbre pulsations.** See vibrato.

**intercolumniation.** *Arch.* The space or method of spacing between columns.

**interim zoning by-law, ordinance.** See CIVIC PLANNING.

**INTERIOR ARCHITECTURE AND DECORATION (INTERIOR DESIGN).** Interior decoration, interior architecture, and interior design are not strictly synonymous, although they are commonly used to describe the process of deliberate planning of utilitarian and deco-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

rative elements within rooms. In its best sense, interior architecture or interior design cannot be dissociated in any way from the function of the architect, insofar as the ideally planned interior, reflecting the usability of the room and its relation to the other spaces, is the key to the plan of the whole structure. Interior decoration, on the other hand, more frequently sees a room as an arbitrary enclosure within a structure and imposes upon this room a plan of applied decoration and furnishing with no more reference to the structure than a stage setting bears to the shape of the theater.

The orthodox method of designing interiors is still preponderantly a matter of combining or blending articles of furniture of harmonizing style with background features—flooring, wall and window treatments, lighting and accessories, of sympathetic form, color, texture. In this method the utilitarian aspects of room and furnishings are largely taken for granted. Deviations from the ordinary procedure are canalized, more or less ingeniously, to fit the preconceived scheme. The output of furniture in recent years having been chiefly eclectically stylistic, most American interiors have inevitably assumed arbitrarily stylized pretensions, so far as mechanical innovations of lighting, heating and construction could be circumvented.

In ancient times the rooms that served the higher civilizations of the Mediterranean basin were of the simplest organization, as life was largely lived out of doors. In all likelihood, the rooms of Egyptian, Greek and Roman antiquity were small and built around central courtyards. There were probably no windows. In this elementary house organization interior design was, therefore, purely a matter of decoration, and that, most likely, surface effects only, aided by powerful colors. The quantity and nature of the furniture is conjectural, but it is reasonable to suppose that such articles were few in number and portable rather than fixed. In public buildings, inevitably religious, interior design was inspired entirely by ritual. The effects were monumental, consistent, imposing.

Buildings of the Middle Ages were essentially religious in motivation. The architecture of the structure was a completely integrated design; the whole shape, details and interior aspect emanated from a single impulse. Inside and out, Gothic building exhibits a concerted directness of planning and embellishment that is the architectural glory of the era. Insofar as this method met the conditions of usefulness, it produced superb functional designs. Rich colors and gold leaf were applied to ceiling and wall area between structural members. Woodwork was richly carved.

Domestic life of the Middle Ages was an entirely different affair from present standards. The mass of people lived in hovels or huts of such elementary character as to be beyond the consideration of this subject. Above that propertied persons appear to have lived a somewhat nomadic existence with military expediency a prime factor. It follows that the rooms they inhabited in their fortified castles were furnished with articles of a portable nature and that the harsh aspect of the interiors was ameliorated by such decorative elements as tapestries (Arras), carpets and rugs. Tile and painted plaster walls and stone floors were the background; textiles were embroidered and woven into tapestry pattern and woodwork was extensively carved.

The shapes and uses of rooms were probably poorly defined. A great hall in a feudal castle might have been the quarters for the lord and his lady and her attendants and the entire retinue. Probably the cooking was the first domestic function to have a room to itself. The ladies slept in a space separated from the rest of the hall by hastily hung curtains, while the retainers arranged themselves for sleep on the floor, on benches, and on the coffers in which were carried the possessions of the household.

At a very early date the specialized room appeared. The great hall remained as the living space for the entire household, but sleeping spaces were probably detached into individual rooms before the 12th cent. Windows were not generally glazed until the 15th cent., so that before that time window opening was minimized, fitted with wooden shutters that admitted a trifle of light through holes filled with horn, mica, or waxed cloth. Open fires were built in braziers or on the floor until the development of the fireplace. When this feature appeared during the 13th cent. it became the decorative focus of the whole room, and inspired the symbolism of hearth and home.

The great halls were usually of monumental proportions. The ceilings made no effort to disguise their structural plan, revealing open beams or trusses which at an early date became the subject of decorative painting and carving. Flat beamed ceilings, exposing the beams, developed into coffered types. In the Mediterranean lands a dark polychromy was preferred, but everywhere extensive decoration was lavished on the ceiling. The floors were of stone, brick, or tile and in northern homes al-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

ways covered with a thick loose mat of rushes, straw, or leaves. The Crusaders brought refinements from the East in the form of Oriental rugs and textiles.

Interior walls at first were of the structural stone, but before long the need for some insulating quality led to plastering and, very soon after, to decorative painting and frescos. About 1400 the use of tapestries from Arras in France became universal in colder countries. They were used as wall coverings, to enclose beds or to form partitions in large rooms, and to hang over windows and doors. Presently the practice grew of simulating tapestries with paint on the plaster walls.

The use of wood panelling for interior finish appeared about the 12th cent. In the great houses this was evidently a sheathing designed to insulate. It is also likely that forms of panelling derived from the filling-in with boards between structural wood members where the exterior shell was filled in with wattle. Various designs of panels grew naturally out of structural elements, since the wider panels had to be held rigid by regularly spaced heavier members. Early builders saw the decorative possibilities inherent in these panels, and repeated patterns in the larger areas became one of the staples of medieval wall design.

The staircase was another vital element which appeared early, also as a consequence of the division of the great hall into specialized rooms. Quite possibly the first rooms were built in the form of balconies for sleeping quarters, suggesting the multiple-story house. As the specialized character of these additional rooms developed, the stairway grew in importance and finally vied with the fireplace for focal interest in the great hall.

The actual development of the house form with its specialized rooms is a product of the Renaissance. The stabilization of living conditions promoted the growth of physical comfort, and the nobles and merchant classes were quick to embody the new luxury into their dwellings. Beginning in Italy in the 13th cent. a recognizable house form appears, both in luxurious city dwellings and in suburban villas. The central court motive survived, and Mediterranean houses are still basically planned to look inward rather than outward. In Italy and Spain the rooms present their most gracious aspect to the court or patio, with windows and balconies a feature of the design. The earlier Renaissance rooms, invariably large and high-ceilinged, were on a splendid scale. Walls were painted over plaster, floors were stone, and the ceilings were of rich designs developed from the pattern of the beams, elaborated by paint and mouldings. The furnishings of these rooms were consistently rich and splendid, proceeding from simple restrained forms early in the period to very elaborate carved and inlaid efforts later. While there was a multiplicity of rooms, there was relatively little specialization and few rooms appear to have been used for one exclusive purpose.

The same years in France saw a very similar development in the nature and use of rooms, although Gothic details persisted. The uses of rooms were undefined although their number multiplied. Decoration was rampant, the whole criterion of a room being the amount of ornament applied to ceilings and walls. Furniture was sparsely used, and not usually related to the design of the room. Dominant cabinets such as dressoirs and armoires appeared early and had an architectural affinity with the room, but other furniture was quite unrelated.

Like the Italian, the French architects were primarily concerned with an interior that expressed sumptuous magnificence rather than any human living quality, and employed various motives and materials as embellishment more than for any conceivable comfort that might derive from their use.

The Alpine countries had a lesser aristocracy and a more important bourgeoisie, and their efforts at interior design were largely directed toward making their rooms a refuge from the severe winter climate. At an early date we find such rooms sheathed with wood of great decorative pretense, a very considerable effort toward the humanization of the room and its furnishings.

The English house development quickly succeeded the feudal castle. The 16th cent. witnessed the growth of half timber, brick and stone dwellings of advanced form. Gothic details survived although the architectural planning was new, and rooms for specialized purposes developed quickly. The great hall persisted throughout the Tudor period and even later, although it had long ceased to be the whole of the house. A multitude of rooms were added on a rambling plan without too much regard for the architectural symmetry that typified Continental work. The quality of informality is the key to the livable aspect of English domestic architecture, as opposed to the purer plan designs of France and Italy. It persisted in spite of the Renaissance accent on classical propriety. Rooms were often of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

odd shapes dictated by convenience rather than by exterior appearance.

The general aspect of early Tudor rooms was vigorously masculine, dignified and austere. Windows were as emphatically part of the composition as fireplaces, both important factors in a chill gray climate. In lesser buildings wall treatment appeared in the form of interior half-timbering, in which the structural skeleton was visible, the intervening spaces being filled with rough-textured plaster. The panels were occasionally carved with either the vestigial linen-fold panel or newly borrowed ornaments of the Renaissance. To a lesser extent panels were painted. Plaster work became significant, the method of moulding ornaments into ceilings or walls being known as **parge work.** Wood floors appeared in the upper stories. Furnishings and accessories were few. On the whole the 16th cent. English room reflected a boisterous, masculine social life, with small emphasis on comfort.

The 17th cent. generally saw the emergence of the room form as it subsequently developed. Manners and customs quickly reflected growing wealth and political stability. The feudal aspect of the room disappeared, except for those state chambers which bore a certain political significance and were first dedicated to the use of large numbers of people. The domestic quality of life reduced the size and scale of rooms to a few elementary features: the range of the human voice, the dimensions of the human frame, considerations of heating and ventilation, and the particularized activity for which the room was planned. This was accompanied by a general softening of textures, a toning of the chromatic scale, and the inclusion of articles of furniture or fitments planned to facilitate the activity within the room.

In Italy the suburban villa flourished under the influence of architects like Palladio and Vignola. Their houses, particularly those in the Veneto, were exquisite compositions of well-planned rooms behind a symmetrical facade, in which neither the design of the room nor the exterior was sacrificed one to the other. The rooms were superbly adapted to the climate and to the stately cultured Mediterranean scheme of living.

In France the great palaces carried the regal concept to extremes in the palatial scale that typified Louis XIII and Louis XIV. Colossal ostentatious rooms were calculated less to render human comfort than to bedazzle and astonish. The regal manner was stepped down in scale in lesser buildings, but never abandoned. The more significant development followed the growth of the *petite bourgeoisie* who utilized some of the decorative inspiration but retained their sense of livability and creature comfort. The group of styles labeled French Provincial comprises an infinity of regional variations and reminiscences of court manners from Henry II to Louis XVI, but never loses sight of human scale and utility.

English domestic life, like the French, advanced by rapid stages during the 17th cent. The Cromwellian Revolution, discarding opulence and ostentation, advanced notions of simplicity and utility in room design which were not altogether lost in the subsequent return of extravagant living. The Restoration produced rooms strongly influenced by Italian and French contemporaries but later prompted by influences from the Netherlands which tended to simplify and render more comfortable the whole room as well as the individual articles of furniture. Paintings of the Flemish school (q.v.) depict interiors of dignity and comfort. Rooms were smaller, lower, better lighted and ventilated. Ceilings were plain, walls were most frequently of wood, and floors almost universally of wood made more comfortable with Oriental rugs. The architectural influence was strong and the simulation of structural members was a motive of the panelling. Wallpapers appeared, at first in imitation of the tapestries and embroideries. The bed, an outstanding feature of this era, was virtually a room within a room, a voluminous composition of draperies.

With the accession of the Dutch monarchs came a further tendency toward simplicity and delicacy. Reaction to the baroque extravagancies of the Restoration produced simple forms in furniture and rooms of intimate scale and unpretentious harmony. While panelling persisted, it was now more often painted white, and the use of wallpapers became virtually a rule. Rooms of the Queen Anne period show a reduced fireplace, improved window areas, built in features like niches and bookcases, and a superior quality of domestic functionalism that set the style for 18th cent. interiors not only in England but throughout Europe.

In France the baroque opulence of Louis XIV tended, in the period of the Regence, toward a reduction in scale and a softening of contour. A process of feminization set in; this was the counterpart of the simplification of English rooms, but untouched by the democratic germ.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

The 18th cent. witnessed the evolution of the house form and its interiors up to the prototype of the traditional house as known today. The decline of a dominant aristocracy was met by the rise of the lower classes; and in between, the development of a great middle class whose social idiom established the living technique of the next two centuries. This was accompanied by a new consciousness of material comfort. Habits of eating and drinking, sleeping, work and entertainment were modified by a new worldliness. Food, books, woods, music and ideas became the elements of cultured design rather than merely royal prerogatives. 18th cent. rooms are notably smaller and more intimate. In England and France a rich baroque manner persisted in the earlier years of the century. The romantic influence reached its apogee at this time. The fondness for curved lines culminated in the rococo style. Architectural motives were abandoned. Rooms of Louis XV's reign have, in the best examples, wood panels with irregular carved forms and broken corners. In the lesser chateaux painting was resorted to for economy, the strong primary colors of earlier years being succeeded by pastel tones of rose, sage green, putty, mustard and straw tints. Decorative motives after Chinese and natural sources were freely rendered, and wallpaper displaced both. Mantels were now decorative gems, small and exquisitely carved in marble, and were emphasized with handsomely carved and painted overmantels with mirrors, called **trumeaux.** Textiles for draperies and upholstery were of fine scale and texture and patterned with scrolls, ribbons, flowers, etc. Printed curtains, the **toiles-de-Jouy**, had pictorial designs on light grounds. Exquisitely chased metal work formed lighting fixtures, fireplace accessories and hardware. Floors were of wood arranged in marquetry patterns or rectangular parquet and were covered with the remarkable rugs from the Aubusson and Savonnérie looms.

In England early Georgian rooms were rather more architectural, under the influence of Wren, Langley, Swan, Kent and others. This merged into the Chippendale period, and although Chippendale was primarily a furniture designer and manufacturer, he influenced the design of whole rooms to some extent. The great rooms of the period were freely architectural with sumptuous ornament. In the classic Italian manner, columns and fluted pilasters and entablatures with broken or scroll pediments were supplemented by sculptured figures of classic antiquity. Chippendale was influenced by the rococo fashion, but not to the exclusion of other sources. Indeed, the rococo never dominated English work, and Chinese lattice work as well as misunderstood Gothic details appear frequently.

The rococo was most enthusiastically received in the *Schlösser* of the German principalities where it exceeded even the French examples in capriciousness and fanciful extravagance. In Italy the rococo developed a special theatrical quality of moving fanciful lines, lightly rendered. Proportions were less suave than the French work, and ornament, charming in itself, was applied unsuitably and, on occasion, produced an effect of gaudiness and vulgarity. It was a superficial expedient style.

The extravagance of the rococo began to wane before the death of Louis XV, and the style of his successor, Louis XVI, is one of consistent classical austerity. Straight lines and right angles supersede the sinuous curves. The essential characteristics of the interior design continue to develop insofar as the rooms were smaller, less formal, specialized in purpose, charming in scale and detail. Bedroom, boudoir, library and dining room became distinct types. They were furnished with articles reflecting the intimate social life of the period—the chaise-longue, the bèrgere, small desks for note writing, tea-tables, gaming-tables, all symbolizing the current mode of living. Wall treatments of the Louis XVI period were less profusely ornamented whether on wood or plaster. Fabrics as well as wallpapers were applied to the walls. Both wood and plaster areas were painted in soft neutral colors. Naturalistic themes were replaced by elements of classic ornament. Marble mantels were of classic rectangular design, as were also doors and windows. Ceilings were usually plain, although some elaborate rooms were painted with sky and cloud effects.

In England classicism was a continuous line of development. The classic architectural style reached its height in the work of **Robert Adam**, who may be considered the first interior decorator. The brothers Adam were architects, but carried their architecture through every detail of the interior, summoning the talents of artists and designers in every field to execute the details of their broad concepts. Robert Adam designed rooms that share the classic attitudes of the Louis XVI style. Color schemes, as well as proportions, were excessively delicate. The fineness of Greek and Roman detail was offset by broad surfaces of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

delicate hues of pea green, blue, straw, lilac, gray and often white. An air of formality, of cold symmetry, pervaded the Adam work, and contemporary critics objected vociferously to the austere perfection which appeared to them as too contradictory to the comfortable opulence of the Chippendale era. The last half of the century saw fewer innovations resulting from the manner of living than in the ornamental aspects of room design; indeed, there was no substantial difference in the decorative or utilitarian aspect of the important rooms in great houses from the late 18th cent. to the early 20th. and it may be said that the palatial interior never surpassed the splendor attained in the 17th and 18th cents.

The 19th cent. is characterized by the decline of the aristocratic ideal and the ascendancy of the middle class. The new wealthy were satisfied to aspire to the artistic achievements of the aristocracy, a backward-looking process which resulted in confusion, vulgarity, a vast output of works of questionable taste. Fads and short-lived styles spotted the design history of the 19th century. The significance of this decline in taste lies in the corruption of the standards of basic organic design. The most fortunate leavening influence was the fact that so many houses were built by people of modest wealth, who were prevented by the stern dictates of economy from departing altogether from their sense of the substantial and useful.

Interior design in America exemplifies the rise from absolutely utilitarian design through its various stages of embellishment. Colonizations are not made by migrations of great wealth. According to their means the houses of the various parts of the new continent were more or less rudimentary. The New England colonists were yeomen of strain dedicated to austerity and with a background of rustic building. Their first houses were shelters pure and simple, and such artistic value as graced these dwellings was the result of unconsciously good purposefulness, mechanical skill and ingenuity, and directness in the appreciation of useful form and of the materials at hand. The great fireplace and the small windows testified to the primary requirement,—shelter from the stern climate. At least two generations passed in New England before the house took on an air of comfort and convenient living. The walls were finished with rectangular wood panels of upright boards; the ceilings were open timbers; the fireplace was a large part of one wall and usually spanned with a heavy beam ornamented with primitive carving. The floors were of broad boards with an occasional small Turkey carpet. The Virginia colonies of the same era, exemplified in the Williamsburgh restoration, were in the more highly decorative vein which the Cavaliers, with their greater wealth and their broader sense of beauty, were able to import. The Dutch settlements were chiefly homes in the burgher tradition, substantial merchant types, addicted only to the broader aspects of the Netherlands baroque influence. Swedish and German settlements were entirely of peasant character, the log cabin being the conspicuous contribution of the Swedish.

In the 18th cent. the rising merchant class began to import not only an occasional piece of furniture, but the books of the great designers, and local cabinetmakers reproduced the substance of these designs in their own manner and materials. Echoes of Chippendale appear in the work of Randolph, Savory and Gostelowe in Philadelphia, Townsend and Goddard in Newport, among others. Later, the Adam influence motivates Bulfinch and McIntire and, finally, Sheraton and the Directoire style reappear in the skillful reproductions of Duncan Phyfe. It might therefore be said that colonial arts are always of less value than their aristocratic progenitors except for the factors of simplification and adaptation which provide special interest. 18th cent. American rooms were, in their best aspects, faint echoes of the finer houses in England. Woodwork was chiefly painted white; all over panelling is rarer than dado panelling with plaster walls above, although architectural members, like pilasters and cornices, were abundant. Mantlepieces were of wood, distinctively carved, and floors of broad boards. The staircase was made an important feature of the central hall. Wallpapers were imported freely along with damasks and satins for draperies, and *toiles-de-Jouy* came with other French influences during that period after the Revolution in which British inspiration was patriotically discarded.

The early 19th cent. responded to Napoleon to the extent of patterning most of its work after his synthetic **Empire** style. Everywhere in Europe and America a stiff architectural conglomeration of motives from ancient Egypt, Greece and Rome was accepted. A classical imperial attitude prescribed strong colors, stern architectural and military motifs. The Biedermeier style (q.v.) in Germany and Austria is a provincial, graceful varia-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

tion, and similar reduction of the imperial manner characterized the **American Empire.** Provincial styles in France were more casual about mixing *Empire* and *Directoire* designs with vestigial Louis XV and Louis XVI details.

Interior design and decoration in the 20th cent. advanced very slightly from the preceding hundred years. In England and the U. S. A. organic room form was given relatively little thought. It was regarded as a box in which certain activities were contained and, in its turn, contained in a larger box. The shape of the outer shell was too often the starting point and the various rooms were fitted into a preconceived mass of house. Unfortunately, this outer mass was designed less from a consideration of activities than from eclectic notions of silhouette and site requirements. The practice of interior decoration then attached each room as an entity, bestowing upon it such elements of historical design as suited the whim of the owner. This unwholesome practice prevailed in the more costly work even more than in the lesser, as the rich were able to buy antiques and were prompted to simulate backgrounds to harmonize with the antique furnishings. A spurious archeological scholarship became the stock-in-trade of the interior decorator, and decoration acquired a bad name through having become aesthetically sterile, eclectically correct. There were in all countries revolts to this slavish copying. Intellectual movements in the later 19th cent. endeavored to dissociate aesthetics from machine products to the extent of overvaluing the amateur. The culmination of this idea in the Arts-and-Crafts (q.v.), Mission and equivalent homemade movements produced a crude graceless manner of decoration. The **Mission style** in the U. S. A. manifested itself in badly lighted interiors of morose colorings. Furniture was heavy and sturdy by virtue of its primitive joinery and lack of subtlety and sheer weight. There was also an admixture of the *Art Nouveau* (q.v.) at the turn of the century which exaggerated natural motives, with generally unhappy results. The whole approach, while it had widespread effects on commercial design, failed to kindle any lasting interest.

Architectural thought after World War I developed a clear cleavage between the exponents of traditional revivalism and rebel schools seeking to re-appraise decorative and architectural impulses. The traditionalists were more correct archeologically and made better copies than ever before, thanks to superior research and documentation. The modernists on the other hand followed many avenues of thought in the 20's and 30's. One school worked along essentially traditional lines modifying only the decorative idiom. These produced rooms organically the same as they had been before, but often possessing qualities of decorative freedom and ingenuity. Much of the French and German work (which inspired like work in England and America) was reminiscent of the *Art Nouveau.* Fine materials were used. Restrained pastel color schemes and rich textures prevailed. Among these may be cited the work of Ruhlmann in France, Bruno Paul and Peter Behrens in Germany. There was another school that shrieked of dynamics and the Jazz Age, emulating cubistic patterns in harsh forms and strident color schemes. Neither of these schools gave much evidence of a sound philosophic revaluation of architectural design, and the rising school of deliberately functional analysts experienced some difficulty in making itself heard above the clamor of the three other mentioned disputants.

It nevertheless became clear, largely through the external pressure of world events, that humanity must, willingly or not, accept and learn the new living technique. Houses must accept mechanical and social innovations as a factor in design, not by a process of reconciliation. Rooms and houses are no longer composed of boxes. The new approach to houses begins with one or more functions and establishes their relationships in rooms.

The functions of architect and interior decorator in the new houses are not easily dissociated as the external form of the houses derives from the minutiae of the activities within. The room is the first consideration in the design of the house. Its shape and boundaries, lighting, color and furnishings determine its appearance. Heating systems are not limited to the range of a fireplace or stove, so that a large area may be heated and ventilated as readily as a small one. Features like sunlight and seasonal breezes may well become the deciding feature in the appearance of a room. Colors and textures are disposed according to their composition with light and shade, and in terms and shapes and proportions. These factors eliminate the four square wall concept. Symmetry has no purpose, visual or functional, but balance may be achieved without symmetry and the sacrifices it sometimes demands.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

The interior decorator in the traditional sense must operate in direct conjunction and complete harmony with the architect, if he participates in this type of design at all. More practically, the architect must conceive the interior aspect of the house as well as the shell. There is no separate decorative approach. It is possible and practical that separate individuals can work harmoniously together for a clearly understood end in the same way that the great Gothic cathedrals were one blended thought inside and out. This will demand either that the architect function as interior designer or that the interior designer enlarge his scope to design the whole house. **interior decoration.** See INTERIOR ARCHITECTURE AND DECORATION.

**interior design.** See INTERIOR ARCHITECTURE AND DECORATION.

**interleaved.** *Book.* A book is interleaved when blank leaves are inserted between the printed pages.

**interlude.** An instrumental passage connecting different periods or parts in instrumental or vocal music. See fugue.

**intermezzo.** (1) Interlude. (2) Entr'acte. (3) A short operetta.

**international architecture.** The development of modern architecture in the 20th cent., esp. in the years between 1920 and 1930, in Europe brought forth a trend which influenced the U. S. A. too, called "International Architecture." The borderline between "International Architecture" and "Functional Architecture" is not quite clearly drawn. For its definition, the history of architecture in the 20th cent. has to be scrutinized. The common trend was primarily characterized everywhere by the fight against the historical eclecticism which dressed each building independent of its practical function with the same repetitions of forms of earlier periods.

The reaction began in Austria, Germany, and the Netherlands. It later was carried on in France, Scandinavia, and Russia. Around 1920, two currents had clearly developed: The one based upon earlier works by Otto Wagner, Van de Velde, and Joseph Maria Olbrich was now, in this generation, represented in Austria by Joseph Hoffman and Koloman Moser; in Germany, by Hans Poelzig, Bruno Taut (Expressionism); in the Netherlands, by M. de Klerk, P. Kramer, C. I. Blaauw; in France, by Auguste Perret. These architects, although denying the eclecticism of the 19th cent., developed very soon a new kind of technical romanticism. Certain forms continuously repeated began quickly to stale.

The other group of architects, represented by J. J. P. Oud, W. M. Dudok in the Netherlands, Adolf Loos in Austria, Walter Gropius (Bauhaus) and Mies van der Rohe in Germany, Le Corbusier and André Lurcat in France, Lescaze and Neutra in the U. S. A., denied equally the historical eclecticism. However, their works and those of their followers emphasized the composition in individual loose plans instead of in solid compact masses, stressing more the specific qualities of the respective materials and construction methods. The artistic result of these tendencies was the opening of the façade by large porches and windows, cubic concentration of crystallized masses, emphasis on horizontal lines. It is this type of architectural planning which is generally called "International Architecture."

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Practically, very soon national shades of this international movement became apparent. Although strongly functional planning produced a certain alikeness, the respective national traditions, preferences for certain materials and construction methods began soon creating variant external shapes. Thus today, modern architecture after having gone through its fighting and pioneering stage begins gradually to lose its dogmatic, cool strictness and to fit into the lines of the respective national traditions. In spite of this fact it should never be forgotten that the whole modern development in architecture is entirely based upon the fundamental and essential achievements of the generation working between 1920 and 1930 in Europe, and after 1930 in the U. S. A. See functional architecture; also Bruno Taut, *Modern Architecture,* 1929; Henry Russell Hitchcock, Jr., *Modern Architecture, Romanticism and Reintegration,* 1929; Le Corbusier, *Towards a New Architecture,* 1929, and *The City of To-Morrow,* 1929; Cahill, Holger, and Barr, A. **International pitch.** See ACOUSTICS.

**International style.** See INTERNATIONAL ARCHITECTURE.

**Interpretative dance.** See natural dance.

**Interval.** The distance between two tones is called an interval. An interval is referred to as melodic if they are sounded successively and harmonic if sounded together. In naming the intervals the major scale is the usual standard. Intervals are reckoned from the lowest to the highest note and given a "number" name such as a second (c-d); third (*c*-d-*e*); fourth (*c*-d-e-*f*) etc. Should two voices sing the same pitch, the unison is called a prime. The "number" names is qualified by a "specific" name for which the terms perfect, major, minor, augmented and diminished are used. In the major scale the intervals formed by using the key-note as the lowest note are either perfect (prime, fourth, fifth, octave) or major (second, third, sixth, seventh). To calculate the specific name "whole" and "half-steps" are used to measure the interval, thus a major third is two whole-steps or four half-steps.

By the use of sharps, flats or double sharps and flats intervals may be decreased or increased. If a **major** interval is decreased by a half-step it becomes **minor,** (C-E reduce to C-Eflat). If a **perfect** or **major** interval is increased by a half-step it becomes augmented. (*Perfect* C-G; C-Gsharp, augmented: Major sixth C-A; C-Asharp, augmented). If a *perfect* or *minor* interval is decreased by a half-step it is diminished, (*Perfect* C-G; C-Gflat, diminished: *Minor* third C-Eflat; C-E double flat diminished). It will be noticed that on the present day piano the interval C-Gsharp and C-Aflat will sound the same whereas on string instruments the slight difference may be demonstrated. These intervals sounding the same but labeled with different staff names are called **enharmonic intervals.** In keeping with theoretical practice, however, the interval C-Gsharp is reckoned as a fifth (augmented) and C-Aflat as a sixth (minor).

Intervals beyond the range of the octave (**compound**) such as the ninth, tenth, etc., are ordinarily reduced an octave and spoken of as a second (ninth), third (tenth), etc. In harmony, however, it is common to refer to chords as chord of the 9th, 11th, and 13th with the 15th completing two octaves.

Harmonically, intervals are either **consonant** or **dissonant.** The perfect intervals and the major and minor thirds and sixths are classed as consonant while the seconds, sevenths and the augmented and diminished intervals are dissonant.

Intervals may be **inverted.** That is the lower note becomes the higher or vice versa. Under these circumstances the perfect intervals remain perfect; the augmented become minor; and the minor major. As regard the number name the seconds become sevenths; the thirds become sixths, etc. A common device is to subtract the original "number" from nine to find the new interval.

Acoustically, an interval is the ratio between the number of vibrations of the vibrating media, string, pipe, etc. In **just intonation** the vibrations bear a relationship shown in the following table:

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

| | |
|---|---|
| Octave | 2:1 |
| Fifth | 3:2 |
| Fourth | 4:3 |
| Major Third | 5:4 |
| Minor Third | 6:5 |
| Major Sixth | 5:3 |
| Minor Sixth | 8:5 |

In the tuning of keyboard instruments just intonation, mean-tone temperament and equal temperament have been used at different periods. The just intervals are in tune in one key; those in mean-tone permit modulation (q.v.) to several keys; and with equal temperament, the present system, modulation to all keys is possible. The ear is not capable of discerning moderate differences in vibration and the intervals in equal temperament are only slightly out of tune with their just intonation. The ear likewise is unable to resolve intervals that are octaves apart.

At times aesthetic qualities have been attached to certain intervals but this is a personal interpretation and what may appear to be associated with the individual interval may be lost when placed in harmonic surroundings. Certain intervals however have been associated with particular races of people.

Smaller intervals than the half-tone have been the subject of study and experiment. Instruments have been constructed on the principle of the quarter-tone idiom. It is interesting in this light to refer to a 17th cent. manual which refers to quarter-tones and remarks that they are impractical for vocal writing. —J.V.H.

**Intimistes.** See FRENCH ART.

**intonation.** (1) The method of tone production of a voice or instrument. (2) Pitch. (3) Tone quality or timbre. (4) The opening notes of a Gregorian chant.

**intrada.** (1) The pompous introduction to early dramas and operas. (2) An instrumental overture to instrumental compositions.

**intrados.** The interior face of an arch or vault.

**introit.** See psalmody; Mass; MEDIEVAL MUSIC.

**invention.** *Mus.* A composition of fanciful or impromptu character (Bach).

**inverse process.** See PERSPECTIVE.

**inversion.** *Mus.* Device of composition by which a harmonic interval is transformed into its complementary interval within the range of an octave (**harmonic inversion**, e.g.: a minor sixth becomes a major third, a perfect fifth becomes a perfect fourth, etc.), or a melodic interval is transformed into an equivalent interval of opposite direction (**melodic inversion**, e.g.: an ascending major third becomes a descending major third, etc.; in the modal and tonal idioms melodic inversion is usually applied with the proviso that minor intervals stand for major, and vice versa, whenever literal inversion would interfere with the mode, or key, of the original melody). Sometimes the term inversion is applied to the transposition of melodic lines in double counterpoint (see counterpoint); this usage, however, is misleading and should be avoided. —E.K.

**inverted interval.** See interval; inversion.

**Ionian mode.** See idiom A (2).

**Ionian vases.** During the 7th and 6th cents. B.C. there were many productive potteries on the coast of Asia Minor and the islands of the Aegean, which produced vases combining Greek and oriental motifs in an interesting way. Notable among them were those at Miletus, Ephesus, Colophon, Priene, Clazomene, Rhodes and Melos. Oriental influence, causing the breakup of the geometric tradition, first appeared in the Cyclades, where 7th cent. vases found in Delos, Melos and Thera show heraldic animals and birds beginning to supplant the earlier abstract patterns. The so-called **Melian amphorae** have rich decorative bands of birds and animals, some of them imaginative ones such as sphinxes and sickle winged horses, painted on a cream slip with geometric ornament still filling in the background. "**Rhodian**" **ware**, including a lovely series of robust pitchers, has similar friezes of birds and animals, but the color scheme is more brilliant, including crimson, maroon and black against the cream slip. The "Ionic eye" was often painted on them to ward off evil. During the 6th cent. the oriental tapestry effect was generally abandoned in favor of the organization of human figures in mythological scenes (often humorously interpreted) or everyday life: sport, battles, festivals; and plant decoration became conventionalized for borders. Among the most important vases of this period were gay and fantastic vases from **Clazomene**, with scenes of dancing and riotous Satyrs and a liberal use of foliate ornament; **Fikellura ware**, notable for its spirited scenes of dances

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

and animals painted on squa -neck amphorae; a polychrome series found at Naucratis, in which the color scheme includes red, black, white, yellow, maroon and purple on a cream ground; ware found at Cyrene, picturing incisively scenes of everyday commercial activity; **"Caeretan" hydriae**, stout water jugs with white, black and dark red pictures representing mythological scenes, such as the exploits of Heracles; **"Pontic" ware**, with lovely plump lotus and palmette borders and mythological scenes which are frank caricatures, such as the Judgment of Paris vase; and a fine series called **Chalcidian**, elegant in shape, with energetic pictures crisply painted in black on the deep orange ground. —W.R.A.

**Ionic cyma.** Term applied sometimes to the cyma recta (q.v.) or to the cyma reversa (q.v.), both of which mouldings are commonly used in Ionic order.

**Ionic frieze.** In classical architecture, the middle member of the entablature, over the epistyle or architrave; in the Ionic order left a plain band with a crowning moulding or decorated with a continuous band of figures or ornament in relief. —L.T.S.

**Ionic Renaissance.** See HELLENIC ART.

**Iranian art.** See PERSIAN ART.

**iris.** See SYMBOLISM IN FAR EASTERN ART.

**Iris green.** A rare pigment with fine green color, this can be classed among painting materials now obsolete. It was used extensively for manuscript illumination during the 14th and 15th cents. It was an organic dyestuff made from the juice of the iris flower and the best color came from mixtures with alum. —G.L.S.

**Irish jig.** The word "jig" designates a large group of Irish national dances, group and solo, each of which has its individual name and particular arrangement of the traditional content. Jigs are characterized by fast shuffling, tapping, jumping, and hopping steps in 6/8 or 9/8 meter. The solos are intricate and difficult, with great stress upon the complicated foot-work. The group jigs are simpler, and may be round, square, or long dances, sometimes differing from the reels only in meter, but usually employing the jig type of step. See Irish reel. —J.G.

**Irish reel.** The reel is a type of Irish national dance in 2/4 meter. The name applies to a large group of dances, each having its individual title and arrangement of traditional steps and figures. There are reels for solo and for small or large groups of couples. The steps of all reels are gliding and rapid with little torso movement, but more intricate in the solo dances. The group reels are round, square, or long dances, elaborate in pattern, with weaving and turning figures, promenades, advancing and retiring of couples in turn, etc. —J.G.

**Iron gall ink.** See ink.

**iron pigments.** The best known of these are the earth reds and yellows, and green earth or terre-verte. The red iron oxides found as natural deposits are haematite, Indian red, light red, Tuscan red, Venetian red, English red, and others. Synthetic iron oxides have been made and bear the trade names, Mars red and Mars yellow. The yellow iron pigments, also oxides, are somewhat more hydrous and go by the names, yellow ochre, raw sienna, and the dark raw umber which contains also a small amount of manganese. Burned to a dull red color, the two latter give burnt umber and burnt sienna. Green earth contains not only hydrous iron but magnesium and aluminum potassium silicates. —G.L.S.

**iron wire stroke, the.** In Chinese painting, the long, even, and flowing line drawn by a vertical brush, mastered first by Ku K'ai-chih of the 5th cent.

**ironwork.** See METALWORK.

**ishi yake** (Jap.). Stoneware.

**ishizuri** (Jap.). An impression secured by taking a rubbing from a stone. Also used to define any print which is similar in style. See rubbing. —J.A.M.

**ISLAMIC ART.** The categorical fine arts have all been practised in a characteristic manner by Islamic peoples. But Muslims did not conceive our distinction between fine and useful arts. The Encyclopedists who afford the best indices of the intellectual importance attached to the various human activities include painting among such crafts as weaving and metal-work; sculpture as such is rarely mentioned. Architectural design, in theory at least, was a part of geometry (*handasa*) and in practice often the work of master-masons. "Classic" Persian painting

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

was in practice a subordinate part of book-making. Of all the visual arts calligraphy (*khatt*) alone appears to have been regarded as a fine art by Muslims( it is termed "a spiritual geometry," see also Koran LXVIII) and enthusiastically practised for its own sake by princes and statesmen. The Arabic alphabet in various scripts, generally in "contrapuntal" or "polar" combination with arabesque (*islimi*) ornament, became the most august decoration for architecture and other deliberately beautified artifacts.

Muslims, then, have never looked to artists (with the exception of poets and perhaps calligraphers) for special insights or meanings. They regarded the arts as we regard the decorative arts.

In spirit this art has been characterized as "polar". Tension between simple bulk and minute two-dimensional surface-elaboration, between curved and straight lines, has perhaps never been so extreme as in the "classic" manifestations of Islamic art (Persia 11th-16th cents., Syro-Egypt 12th-14th cents.). The mature color-systems exemplify the same polarity in hue (*ablaq* masonry; checkered, etc. revetments; equality of saturation giving a curious "pull" to juxtapositions of scarlet and blue, orange and green in Safavid paintings and textiles). The spirit was present at the beginning of Islam (Korans of the Abbasid period) and even in Sasanian Persia (*ivan* facade with its violent antithesis of air and solid, e.g. Ctesiphon).

Probably because Islam historically is to be regarded rather as a reaction in Eastern Christianity than as a new culture, and because the Arabs among whom the Faith arose did not practise the visual arts, earlier Islamic architecture, sculpture, and painting are best approached as final forms of the Byzantine-Sasanian style, alternative forms to those prevailing in the Christian lands which were not conquered by the Muslims.

In the 10th and 11th cents. a revival among the Iranian peoples opened a new phase. The transformation of the older Islamic style then accomplished was spread, in successive phases of development, by their conquerors, first by the Seljuq Turks, then by the Mongol Il-Khans, then by the Timurids. Lastly, by its own splendor in its period of conclusive fulfilment (16th cent.) it permeated afresh the Moghul and Ottoman courts.

There is thus a certain want of organic unity in the development of the Islamic fine arts which underlies the apparent consistency of the Islamic style.

*Architecture.* The essentials of the Muslim town are a mosque, a bazaar, and a public bath. In addition to palaces (for which the Central Asian conquerors of Persia contributed a special type: a garden with tents for habitation and kiosques, often of great grandeur, for ornament), castles (in which the Muslims developed Sasanian and Byzantine forms), bridges, and other great forms common to all highly developed architectures, certain characteristic Islamic forms were developed, including: (1) the **mosque** (*masjid* and, later *jami*) or normal place of worship (*sajd*: prostration), consisting of a court (*sahn*) surrounded ordinarily by roofed arcades (*rivaq*). Mosques are generally oriented towards Mecca (this direction is called the *qibla*), and in the sanctuary, or arcade on this side, are generally a niche (*mihrab*) showing the qibla, a pulpit (*minbar* )and often a *maqsura* or fenced-off area in the arcade. From one to six minarets, tall towers for the call to prayer and for architectural ornament, were often built near mosques, or at their sides or corners. The mosque form may be regarded as the incorporation of certain features of early churches in plans modelled on that of the Prophet's house at Medina which served as the first center of worship. (2) the *madrasa* or *college,* originally a school of Sunnite theology, but used by the Seljuqs and their successors as schools for the administrative bureaucracy. At first of merely domestic architecture, they were later characterized by the use of a pre-Islamic cruciform plan, with four great *ivans* round a court. (3) the *monastery* (at first *ribat,* or military station for the Holy War against unbelievers; later *khanaqah* of Sufi mystics on the Persian model, and, in the Ottoman empire, *takya* or dervish hostel): architecurally *ribats* appear to have been fortified caravanserais with tall watch-towers; *khanaqahs* were in general cult-buildings of mosque or madrasa type with subsidiary courts surrounded by rows of cells. (4) the **monumental tomb** (*turbat, qubba, gunbad, pir,* or even *sayyid*) generally a square chamber with a domical roof. A distinctive Persian type common from the 11th to 14th cents. is a tall tower. Tombs are sometimes the most ambitious of all Islamic buildings (Sinjar at Merv, Taj Mahall, Bijapur dome) and are of importance since they were frequently placed at the corners of the qibla side of mosques or madrasas. (5) the **bazaar,** *suq,* or *qaysaria,* a street often vaulted or ceiled, with shops on both sides. Bazaars are often in the form of a cross, and seem to

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

develop from the crossed streets of booths which have been for many centuries the Asiatic nomad markets. (6) the **caravanserai** or **khan**, an open or vaulted court with one or two stories of small rooms surrounding it.

The most characteristic formal specialities of Islamic building, are, in addition to the minaret and the *ivan* or open-ended vault, peculiar dome-profiles, squinches of great variety of filling, webbed armatures in pendentives, half-domes and vaults, "stalactites" (*mugharnas*), and carved plaster diapers.

The first great building of Islam is the Dome of the Rock at Jerusalem (691 A.D.), a wooden dome on a pillared and arcaded ambulatory, richly decorated in mosaic, essentially Byzantine. Similar mosaics decorate the Great Mosque of the **Umayyads** at Damascus (705-715), which has a great three-aisled prayer-hall crossed by a transept parallel to the *qibla* having a domed center. Other Umayyad monuments are Qusair 'Amra (712-715), a bath with erotic, astrological, and propagandist murals, and Mshatta (743-744), a palace in the desert, half the elaborately carved facade of which is in the Berlin SM.

With the fall of the Umayyads Iraq became the seat of empire, and a more Sasanian, a less Christian imperial or metropolitan style prevailed. The Round City of Baghdad, with palaces, barracks, and offices in its center, and its popular quarters disposed circumferentially within the triple defense system and the four gates, expresses the Caliphal determination that no *émeute* of the type to which they owed their own power should ever take place again in the capital. The Round City has totally disappeared, but has been reconstructed by Herzfeld and Creswell. Apart from the mosque of Qayrawan in the west (v. inf.) the middle 9th cent. ruins of the palaces and mosques of Samarra give our clearest picture of **Abbasid** architecture. It was extravagantly ostentatious in scale (the Bulkuwara palace is about 1250 m. a side), lavishly and rather coarsely decorated with carved plaster, mural painting of debased Sasanian-Hellenistic type, and precious materials. Its effect was probably largely dependent on hanging and rugs. Huge conical "minarets" with winding ramps up which donkeys could be ridden were for pleasure rather than for religious use. Ukhaydir and Raqqa are important Abbasid monuments.

Carved plaster remained a principal ornament of Islamic interiors up to the present day. The mosque of Ibn Tulun at Cairo (876-879), with plastered brick arcades, is the finest early Islamic building in Egypt.

The schismatic **Fatimid** caliphs appear to have favored the massive ashlar construction with delicately-cut surface ornament which was to set a style for the noblest West-Islamic buildings (Cairo: mosques of al-Azhar, 970-972, al-Hakim, 990-1003, al-Akmar, 1125, gates of Bab al-Futuh, Bab al-Nasr, Bab Zuwayla).

Little remains of **Ayyubid** work in Egypt. Citadels, mosques, madrasas, and hospitals (mostly on a modest scale) at Damascus and, more important, Aleppo, show the perfect mastery of Syrian stone-cutters over the now perfected Islamic arch, surface-arabesque, and stalactites (Jami' of Aleppo; Firdaw's mosque and madrasa, Aleppo, 1235).

Under the **Mamluk** successors to the Ayyubids Syro-Egyptian architecture reached its conclusive form. Increasing use of varicolored (*ablaq*) masonry, red and white or black and white marbles and limestone, interiors of stone marquetry (later imitated in paint), stripes, checkers, polygonal entrelacs, guilloches, a preference for lines of stability e.g. in the strongly horizontal organization of stalactite squinches, half-domes, and cornices and in the avoidance of strong diagonals, these features are what distinguish the Mamluk, one of the supreme expressions of the Islamic style, from contemporary Persian architecture. A very deeply stilted dome, and a characteristically Egyptian way of emphasizing cubical form by the suppression of corner-punctuation are the most significant formal peculiarities. The principal monuments are all in Cairo: madrasa of Baybars, 1262-3; madrasa of Sinjar al-Jawli, 1303-4; madrasa-tomb of Sunqur Sa'di, 1315; mosque of Muhammad Nasir, 1318; Almas mosque, 1329-30; madrasa-tomb of Sultan Hasan, 1356-62; Khanaqah of Barkuk, 1400-10; mosque of Sultan Mu'ayyad, 1414; madrasa-tomb, 1472-4, and city mosque 1475, of Qa'itbay; madrasa of al-Uzbek, 1487-1500; madrasa of Abu Bakr Ma'shar, 1497; madrasa of Qansawh al-Ghawri, 1503-4; the so-called "Tombs of the Caliphs", 15th and early 16th cents.

The Ottoman conquest introduced the **Ottoman** style (v. inf.).

In the east, mosques were at first **Sasanian** in construction even if raised over an Arab plan (Tarik Khana of Damghan, pier and barrel vault *rivaqs*). The decline of the Abbasid caliphate coincided with the revival of Iranian national culture, of which the most important architectural monument is the tomb of Isma'il the Samanid at Bukhara, c. 900,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

a dome on tripod squinches, with very elaborate bricklays and a vaulted gallery round the springing. The chief buildings of the pre-Seljuq period (towers of Gunbad-i-Qabus, 1006-7, Radkan West, Pir Alamdar at Damghan, 1026; *turbat* and minaret of Sangbast; minaret of the Tarik Khana; towers at Ghazni; Dawazdah Imam at Yazd, 1037) prove that forms (flanged towers, tall cylindrical minarets, squinch with oversailing quarter-domes), techniques (elaborate bonds, cut terra cotta), and decoration (fine-scale arabesque, plaited Kufic) of the Seljuq period existed, though severally, before the Seljuq conquest. Even glazed tile (*kashi*) inlay for brickwork occurs in the Jami minaret of Damghan.

Under and after the **Seljuqs** in the later 11th and 12th cents. these elements were combined in a series of masterpieces: Isfahan Jami', especially the North Dome, 1088, which is perhaps the most wonderfully constructed dome on the Earth's surface; mosques of Gulpaygan, 1104-17, and Qazvin; Ribat-i-Malik near Merv, with its wall of huge cylindrical pleatings; towers at Rayy 1139, Kunya Urgenj; the Haydaria of Qazvin; tower at Maragha, 1147; Gunbad-i-Alaviyyan at Hamadan; tombs of Jalal al-Din Husayn at Usgen, 1152, and of Sinjar at Merv 1157-60; Ardistan mosque, 1160; Jabal-i-Sang of Kirman; tomb of Mu'mina Khatun at Nakhshivan, 1186-7; octagonal tower at Maragha of 1196-7. Interest in surface-enrichment by outset entrelacs, *kashi*, pleatings, etc., is marked in the latter of the foregoing.

The first **Jinghizids** built little; at the end of the 13th cent. grand architecture recommenced with the now ruined tomb of Ghazan near Tabriz (parts of revetment in the Berlin SM.). The mosque of 'Alishah at Tabriz, with a vault over 30m. wide, now fallen, the dome of Sultania, which had a "coronet" of eight minarets, shrines at Bistam and Natanz, all show the increased elaboration of colored ornament, esp. of *kashi* marquetry or "mosaic", with which the early 14th cent was preoccupied. Of this type of decoration the first "mature" or "late" example, with curvilinear arabesque in five colors, is the Baba Qasim shrine at Isfahan, 1340-1. Its development in the buildings of the Muzaffarids in Fars and Jibal brought it to an indescribable liquid brilliance (Jami' of Kirman, 1349; extensive rebuilding of the Jami' of Yazd; the former is the oldest complete example of an important mosque-plan with a huge portal on the main axis, opposite the *mihrab*, with a domed vestibule leading into the *ivan*).

Under **Timur** and his successors Persian architecture of the Islamic period approached its final form: the differences between the great buildings of about 1400 and those of about 1700 are differences of detail. Now appears, at first in the Oxus region, that dome of bulbous profile on a high drum which has always fascinated the West. Early examples, generally "ribbed" or pleated; Hazrat Yassavi at Turkistan, 1394 or 1397; Gur-i-Mir at Samarqand, before 1404; Shah Zinda cemetery, Samarqand. The most important standing monument is the mosque of Gawhar Shad in the shrine of Imam Riza at Mashhad, 1405-1418, the finest colored exterior surviving, a court with four great ivans, two-story facades, and minarets flanking the sanctuary *ivan*. The whole visible surface is either *kashi* or a deliberate ground or foil to it in brick or plaster. Gawhar Shad's *musalla* at Herat, of which two minarets remain, appears to have been even more splendid. The chief architect and decorator of the early Timurid period was Qivam al-Din of Shiraz. Many Persian buildings were rebuilt or redecorated in the XV century. The most famous monuments are the Blue Mosque of Tabriz, 1437-67, and a madrasa at Khargird, 1444-5.

The **Safavids**, extensive builders, innovated little. Widening of the decorable surface by the elimination or chamfering of reveals was carried to the limit. After about 1600 five-color or seven-color figured tiles tended to replace the more expensive mosaic. Principal monuments are: Harun Vilayat at Isfahan, 1512; Shrine of Safi at Ardabil; the Ali Qapu palace, Royal Mosque, mosque of Lutfallah, and Qaysaria in the Maydan of Isfahan (early XVII century); Khwaja Rabi' at Mashhad, 1622; Court, dome, and embellishments at the Mashhad shrine; Qadamgah near Nishapur 1643; Madrasa-i-Madar-i-Shah at Isfahan, 1707-11.

Under the short-lived Zend dynasty at Shiraz were built several extreme examples of the bulbous dome, only a few decades after the building of the Isfahan madrasa dome of 1707-11, which is in contour the subtlest and best of all Islamic domes. In the Qajar and Pahlavi periods the increasing influence of Europe has affected the traditional forms. Various Teheran palaces (e.g. Gulistan, Bagh-i-Firdaws) show the style best.

ASIA MINOR, ETC. When the Seljuqs mastered Rum (Asia Minor), the old sculptural technique of that region was only gradually adapted to the expression of Islamic de-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

sign. Early examples (e.g. Divrigi, 1229) show ornament apparently designed by illuminators executed in deeply-cut relief and three-dimensional arrangements; the effect is extraordinarily turbulent. Later examples (Chifta Manara, Sivas, 1271-2) though generally richer than Mamluk or Almohad masterpieces, conform to the Islamic norm for relation of bulk to surface. Principal monuments: at Konya, mosque of 'Ala al-Din, Kara Tai Madrasa, 1251-2, "Indian Minaret".

The extinction of the Byzantine empire left the Ottoman successors to the Seljuqs heirs to the Byzantine style, and they built great enclosed mosques with saucer-domes, and often with abutting half-domes, curiously like the grandest churches. Principal monuments: at Brusa, Ulu mosque 1421, Green Mosque, 1423; at Istanbul, mosques of Shahzada, 1548, Sulayman, 1557, Ahmad I, 1617, Nur-i-'Uthmania, 1755; at Adrianople, mosque of Salim II, 1574. Some details such as *ablaq* voussoirs derive from the Mamluk style, others such as tile revetment from Persia, others such as baroque cornices and mouldings from Europe; but at its best the Ottoman style is, though frigid, nobly monumental. Its great masters were Sinan and Agha. A peculiarly slender minaret with elongated conical head, and often with two or three stalactite-corbelled balconies, was much used (sometimes six to a mosque). To Western eyes the minarets of Istanbul are more masterfully grouped than any in Cairo, Persia, or India.

INDIA. In India under the Ghorid successors of the Ghaznevids, her first Muslim conquerors, was produced another variant of the characteristic architecture which Islam imposed upon stone-working countries. The mosque-facade and minaret of Qutb al-Din at Old Delhi (late 12th cent.) and the 'Ala Darwaza at the same site, 1310, are so much akin to Alomohad work that a comparison is startling proof of the unity of an Islamic art-style over almost an entire quadrant of the Earth's 30th latitude. Under the medieval dynasties the style reverted somewhat to Indian character (Sahsaram, tomb of Shir Shah; Bijapur architecture, esp. tomb of Muhammad Adil Shah, early 17th cent., a huge dome with an inner diameter of c. 45 m., larger than the Pantheon or S. Sophia of Constantinople; Golconda architecture of the Qutbshah period). The **Moghul** emperors, whose ideas of culture were strongly colored by their Timurid ancestors and their Safavid contemporaries, imposed typical Islamic refinement on the architecture of the 16th and 17th cents.: tomb of Humayun at Delhi; tomb of Akbar; Taj Mahal, tomb of I 'timad al Dawla at Agra. These and the various palaces at Agra and Delhi are remarkable for rich interiors of marble inlaid with illuminators' flower- and arabesque-designs in variegated and semi-precious stones. Cusped arches, flat as well as vaulted roofs, pierced marble grills, corbels with massive drops, heavily-domed roof-pavilions on slender columns are characteristic of the **Moghul style.** Its normal material, apart from marble, was red sandstone.

WESTERN LANDS OF ISLAM. Though Ifriqia, Maghrib, and Andalusia have really their own artistic characters and traditions, their interaction in the Muslim period and their homogeneity vis-à-vis the Persian style suggest a general treatment. Algeria is essentially provincial.

In Ifriqia the conquerors founded Qayrawan, where about 800 the Aghlabids set up a dynastic culture in the **Abbasid** style. The Great Mosque of Qayrawan is the only great unruined monument of Abbasid architecture (836-875 and later). It has a hypostyle hall (main aisles in a T along axis and *qibla* wall; sixteen lateral nine-bay aisles) and an enormous court with narrow *rivaqs* (total area: c. 135x 80 m). On the axis opposite the *qibla* is a minaret of three square stories, and the axial aisle of the *qibla rivaq* is punctuated with domes before the *mihrab* and next the court. In the aisles, re-used classical and Byzantine columns and capitals support horseshoe arches, with an over-abacus, impost, and cornice mediating. On the arcades rest timber roofs; the axial aisle is pitched. The *mihrab* dome has conch-shaped squinches supporting, on an arcade of sixteen niches, a hemispherical fluted or melon dome. Other monuments; Zaytuna mosque of Tunis, 865; ruins of Sedrata; mosque and *ribat* of Susa.

The **horseshoe** (*manfukh* swollen) **arch,** either round, deformed, or pointed at the head, remained characteristic of West Islamic architecture. Qayrawan's influence is only less than that of the Great Mosque of Cordova (785-961 and later). Here, on the model of Damascus, the Spanish **Umayyads** employed Byzantine mosaicists, but this technique was little imitated, whereas reflections are to be seen everywhere of the "Villa Viciosa" and the sanctuary bay, one of the most fascinating structures ever built by man. At the culmination of the Italian baroque Guarini's San Lorenzo at Turin does little more than repeat this extraordinary form. Within and

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

beneath the main triple horseshoe arcade are interlaced cusped half-arches in relief-carved vari-colored ashlar. Above, cusped squinches form an octagonal "drum" from the angles of which spring eight interlaced arches, whose crowns provide the narrowed base for a fluted hemispherical "lantern". Other monuments: mosque of Bib Mardum ("Church of Cristo de la Luz") at Toledo, ruins of Madinat al-Zahra. A post-Umayyad monument of Saragossa, the al-Jafaria, shows the Umayyad style at its climax: the capricious intricacy of its interlaced arcades, though startlingly beautiful, appears never to have been imitated.

The **Fatimids** continued (mosque at Monastir) and the Sanhaja developed (Qal'a of the Beni Hammad; Sfax) the Aghlabid style. Of the dynasties which followed, the **Almoravids** probably gave their present form to the Great Mosque of Algiers, the Qarawin, Fez, and the Great Mosque of Tlemcen, 1135, which has a stalactite-dome lantern resting on sixteen interlaced arches with pierced plaster panels between them.

The **West-Islamic** style reached its fulfilment under the Almohads (1145-1269) of Maghrib, who for the last time united the whole in a single empire. Principal monuments: Qutubia of Marrakesh; Tinmal mosque; Hasan's mosque at Ribat; the Giralda and Golden Tower of Seville. The majestic Almohad gates of Ribat and Marrakesh are among the noblest creations of Islamic art (Bab al-Ruwa, Udaya Qasba, Bab Aganaw). Western mosques in general have proportionally smaller courts than those of Eastern Islam: in the enormous unfinished mosque of Hasan at Ribat (183 x 139 m.) the three courts occupy only about one-sixth of the total area.

Of later West-Islamic monuments the most famous is the Alhambra palace of the Nasrids at Granada (mid 13th-mid 14th cents.), a complex of chambers covered with carved stucco and stalactite work built round two courts, the Alberca water-court and the famous Court of the Lions. The latter has two pavilions emerging from its narrower facades; this scheme was several times copied in Barbary (e.g. 17th cent. pavilions in the Qarawin of Fez).

After the collapse of Almohad power there appears comparatively little architectural invention, the principal evolution being the extension of tile-marquetry. Principal monuments of the Maghrib: Great Mosque of Taza, 13th-14th cents.; Sidi bil Hasan at Tlemcen, 1296; Mansura minaret at Tlemcen, 1303-1336 or later; various Marinid madrasas at Fez, especially al-'Attarin, 1323-5, and Abu Inania, 1350-5; the Sa'dian Mausoleum at Marrakesh (early 17th cent.), the Madrasa al-Sharratin, Fez, 1670, the Mansur gate at Meknes.

Algeria in the days of its wealth produced a bastard architecture of Ottoman, European, and African elements: 'Ali Bichnin mosque, ca. 1622; Jami' al-Jadid, 1660; Kechawa mosque, 1794, now much altered.

Tunisia has continued to produce buildings in which decadence is less evident. Taut arcading of ancient type and sober proportion distinguish such buildings as the exterior galleries of the Zaytuna; the tomb-mosques of Yusuf Dey, 1610-1637, and Hamuda Bey, 1654. The strength of rooted native tradition is shown, even more than in the houses of wealthy modern Tunisians, in the grand modern "Mosque of Swords" at Qayrawan.

The most distinctive decorative features of **West-Islamic** architecture are its arches, horseshoe, cusped, and "slittered" (an elaborate form with much vertical detail got by the grouping of cusps and stalactites), and the richness of its lozenge and trellis diapers. The minarets, of which the different stories are sometimes used for a display of virtuosity in various vaulting, are of great structural interest.

*Painting.* Earlier Islamic painting, ceremonial, magical, erotic, or astrological in content (fragmentary murals at Qusayr Amra, Samarra, pornographic papyrus at Vienna SB.) derives partly from Sasanian but largely from Byzantine and late classical art. The same heritage, considerably assimilated to linear and two-dimensional Islamic style, appears in the earliest surviving illustrated manuscripts (Cairo Royal Lib. Kitab al-Baytara of 1209; Mashhad shrine Khawass al-Ashjar and Mufid al-Khass; Vienna SB. Galen; Paris B.N. Hariri "Assemblies" of 1222-3, and Bidpai fables of about the same date; Dioscurides "Materia Medica" (in translation) of 1224 (dispersed: Boston M.F.A., N.Y. Met. Mus., Freer Gall. Washington); Paris B.N. "Schefer" Hariri of 1237 with pictures by al-Wasiti). An evident old-Asiatic tendency to break down classical illusionist painting procedures into representation by line and local tone is still incomplete: drapery is not yet pattern, although the folds become progressively less realistic until they finally become the so called *Schnörkelfalten* pattern of whorls in Mamluk miniatures (Oxford

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Bod. Lib. Bidpai of 1354; Paris Bidpai ar. 3467). The earlier Islamic style appears to die out with Mamluk painting. Ottoman painting was to begin as an imitation of a new style which had meanwhile grown up in Persia.

**Persian miniature painting** is in scale the most delicate and in color the most brilliant painting ever executed by man. Fairly fine post-Seljuq painting survives on *minai* ceramics (Bowl, Kelekian coll. N. Y.), and a rather decadent style of it in illustrated Shahnamas, with scenes on red and yellow backgrounds (Istanbul 1330 ms.; Leningrad 1332 ms.), and similar Bidpais. Towards 1300, however, the Mongol rulers and their wazirs had assembled Chinese, Persian, and Western painters near their courts in Azarbaijan (Morgan Library Bestiary of 1291 and later; Edinburgh Univ. Lib. Biruni of 1307-8; Edinburgh and Royal Asiatic Society Jami' al-Tawarikh of 1306-1314 are the chief monuments of this eclectic or encyclopedic period).

In the 2d quarter of the 14th cent. Ahmad Musa is said to have founded the "modern" style of painting. What may be his illustrations to Bidpai are remounted in an album in Istanbul (former Yildiz Lib. album); they are the oldest Persian paintings with great range of color, and are based on an exceptional analysis of contemporary Chinese method. The Shahnama was illustrated a generation later in the new style by a group of artists who produced the most powerfully dramatic of Persian paintings ("Demotte" Shahnama, dispersed; collections of its miniatures in the Louvre, Fogg Museum of Harvard, Boston M.F.A., Freer Gallery, etc. Finest individual painting, Rockefeller coll. N. Y.). A Khwaju ms. of 1396 (B.M.) illustrated in a very sophisticated style marks the complete emergence of the Persian manner: tall compositions in so-called vertical perspective, excessively slender and upright figures, crowded and delicate detail. This style, which had developed at the Jalairid court at Baghdad, was patronized by the **Timurid** princes and their Western neighbors (Gulbenkian and B.M. Miscellanies made for Iskandar of Shiraz, 1410-11; Teheran Bidpai; Berlin 1420 Miscellany for Baysunghur of Herat; Vienna SB. Khwaju of 1427; Teheran Shahnama of 1429-30; Istanbul Bidpai of 1430; Upsala Univ. Lib. Nizami of 1439; Roy. As. Soc. Shahnama for Muhammad Juki; Tabari of 1469, Chester Beatty coll., London).

About 1470 appeared Bihzad, justly the most famous of Persian painters; the silly epithet "Raphael of the East" has been applied to a man whose genius lay chiefly in a wholly original realism and a power to render the hurried, the vulgar, and the humorous in perfect two-dimensional beauty (Garett Zafarnama at Princeton Univ. Lib.; Cairo Sa'di of 1488-9; Teheran "Garden Scene"; paintings in B.M. Nizani Or. 6810). His most eminent follower was Qasim Ali (Oxford 'Alishir of 1485).

The Bukhara Shaybanids captured many Herat artists, and a Bukhara group of mss. includes the Kalebdjian Mihru Mushtari of 1523; the Vever Bustan of 1524; the Paris B.N. Makhzan al-Asrar s.p. 985, Alishir of 1553, and Bustan of 1555; and the Kevorkian Jami of 1565 N. Y.

Bihzad and others fled to Tabriz, served the first **Safavid** shahs and probably helped to train the great Safavid masters Mir Musavvir ("Fable of the Owls" in the B.M. Nizami for Tahmasp of 1539-43, drawing: "A King at an Encampment" in the Boston M.F.A.); Sultan Muhammad ("Sinjar and the Old Woman" and labelled miniatures in Tahmasp's Nizami, Leningrad National Lib. "Hunting Scene", Cartier coll. Hafiz, Paris); Mir Sayyid 'Ali (miniatures in Tahmasp's Nizami and in the Beatty coll.). Mirak, Mirza 'Ali, Muzaffar 'Ali, and Shah Muhammad were other meritorious artists of the period, and other rich Safavid mss, are the Met. Mus. N. Y. Nizami of 1524-5 and a Jami in the Kevorkian coll. N. Y. The best artists of the later 16th and the 17th cents., Shaykh Muhammad Shirazi, Muhammadi, Sadiqui, Aqa Riza, Riza 'Abbasi, Afdal Husayni, Mu'in Musavvir, Muhammad Qasim, Muhammad 'Ali, are known chiefly by isolated miniatures in the great collections (Bib. Nat. and Louvre at Paris, Boston M.F.A., Freer Gall., Beatty and Vever colls., albums in the Istanbul Libs Fogg Mus).

Persian painters after 1600 imitated European light-and-shade and landscape. Flower-paintings of extraordinary delicacy are the best 18th cent. work. Large oil-paintings (usually portraits, occasionally erotic) were made to fit the niches in palace walls by Mihr Ali and others from the late 18th cent. onwards (Leningrad Winter Palace; V. and A., London).

In Turkey Salim the Grim inaugurated the **Ottoman** school of painting by kidnapping all the Tabriz masters he could lay his hands on in 1514. Turkish painting is es-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

sentially provincial, and throughout the 16th cent. Persians continued to command high salaries at Istanbul (Shahquli, Walijan). "Physiognomy" mss. or series of portraits of the Ottoman Sultans are a characteristic specialty (Istanbul Univ. Lib.; Beatty coll.), and Turkish battle-painters are particularly fond of representing the effusion of blood. Ustad 'Uthman is perhaps the most famous Turkish painter. Another signs himself Amin ai-Khalafa (Boston M.F.A., Fogg Mus.). Most of the great Turkish mss. are in the various Istanbul libraries, and are unknown to the West, but the Paris B.N., the B.M., the Berlin Islamische Kstabtng., Boston M.F. A., Met. Mus. of N. Y. and Beatty coll. all have good examples of Turkish painting.

In India the Moghul "school" was somewhat similarily begun, Humayun hiring the Persians Mir Sayyid 'Ali and 'Abd al-Samad in the mid 16th cent. But a characteristic Indian palette of varied greens and glowing reds and oranges, and the fusion into a single style of old Indian formulae for scenery and figures, European shade and would-be perspective, and Persian delicacy of detail and linear grace produced a number of remarkable mss. and album-paintings. Most Moghul painters were of Indian blood (Daswanth, Basawan). They illustrated a copy of the Hamza Romance, probably the largest Islamic illuminated ms. (dispersed miniatures in the Vienna Indust. Mus., the V. and A., Boston M.F.A., Met. Mus. of N. Y., Fogg Mus.); the Razmnama, a Persian translation of the Mahabharata; lives of Babur and Akbar; the "Lights of Canopus" or modernized Bidpai, and the usual Persian poets and historians; but much of the finest work was isolated miniatures for albums: portraits, incidents of court life, curious or beautiful animals or flowers, wives and concubines of the sovereign, the sovereign visiting saints or sitting with his deceased ancestors, etc. The portraitist Abu'l-Hasan, the animal-painter Mansur, Gowardhan, Manohar, and others are represented by album paintings at Teheran, (Gulshan palace album), Berlin (Jahangir album), Boston M.F.A., V. and A., London, Beatty coll. etc. Under Awrangzib in the later 17th cent. the eclectic style gave way to local styles, fusing with traditional Hindu painting, and ceased to be in any real sense an Islamic art, although imitative work of considerable skill continued to be made in the great Muhammadan cities for two hundred years.

*Calligraphy and Illumination.* The Arabic alphabet, extant before Islam, was written in three distinct styles as early as the first Islamic century: a rounded cursive, a formal style with extremely elongated uprights, and varied formal styles of generally rectilinear character and elongated connectives, all nowadays mistermed "Kufic", Terminology is only provisional, since no acceptable identification of the various historic scripts has yet been made; though minutely, they are not consistently differentiable, and Oriental connoisseurs are not historiographic in our manner.

**"Kufic"**, the imperial script of the Caliphate, was used for Korans up to c. 1000, and for inscriptions at intervals into the 15th cent. The most celebrated masters of the **Abbasid** period were Khoshnam of Basra and al-Mahdi of **Kufa.**

Probably to be associated with the Persian revival, and possibly regularized by the Abbasid wazir Ibn Muqla, is a dramatic script normal in 10th cent. Korans, found in a stone inscription on a tomb at Ghazni.

**Naskhi**, a rounded script of rather level ductus, was the characteristic writing of the Seljuq period. Masters: Muhammad ibn Khazin of Dinawar (d. 1124), Yaqut of Mosul, Abdallah Sairafi.

Under the Mongols a variety of far more violent scripts were used: *thuluth, muhaqqaq, ta'liq,* etc., not clearly differentiated. Chief monuments are the early 14th cent. Korans for Uljaytu at Cairo and Leipzig, and a late 14th cent. Koran for Bayazid I in S. Sophia with abstracted illuminations in Gulbenkian and Beatty collections. The most famous master was Yaqut al-Musta'simi (d. 1298). **Thuluth** in particular was continued in Rum under the Ottomans, Shaykh Hamdallah (late 15th cent.) being the most celebrated master (Koran in S. Sophia). The greatest later master was Hafiz 'Uthman in the late 17th cent. (Koran and album at S. Sophia; modelbook at Nur-i-'Uthmania, Istanbul).

**Nasta'liq**, the most completely Persian of the forms, with a drooping ductus, strongly repetitive curvature, and an almost complete elimination of straight lines, evolves gradually in the late 14th and early 15th cent. Masters: Mir 'Ali Tabrizi its "inventor", the Timurid prince Baysunghur (inscriptions in the mosque of Gawhar Shad, Mashhad), Ja'far Tabrizi (Teheran Shahnama of 1430). Later masters, represented in most of the great collections of mss., are: Sultan 'Ali Mashhadi,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

his son Sultan Muhammad Nur, Shah Mahmud Nishapuri, Mir 'Ali Harawi, the great master of album-pieces (*mashq*) Mir 'Imad al-Hasani, and his rival the designer of many of the Isfahan building inscriptions, 'Ali Riza 'Abbasi.

**Shikasta** (broken) is an almost illegible and dissipated "decadent" script, found in albums of the 17th and 18th cents.

Of the numerous fanciful scripts the most important is **Tughra** in its monogrammatic form as used by the Ottomans.

Calligraphy in the lands beyond Persian influence shared little in the later glories. In Egypt and Syria the **Mamluks** used curious dilated scripts for monumental inscriptions, and in the West "Maghribi" script kept until the 18th cent. much of the appearance of the early centuries of Islam.

**Illuminations** were at first largely in gold, with tricks of brown, red, blue, and green (Kufic Korans). From the Abbasid caliphate at least, whole pages were devoted to illumination with little or no script. In the Mongol period for the first time really bold antithesis of color were used (Uljaytu Korans). In the late 14th and early 15th cents. delicate black or black-and-gold drawing in margins developed (Divan of Ahmad Jalair, Freer Gall.; Iskandar Miscellanies in the B.M. and Gulbenkian colls.), and the richer pages and headings assumed a characteristic minute scale and blue-and-gold tonality. Pinks, violets, orange, and blue-greens invaded the cool harmony in the 16th cent., and many 17th cent. illuminations are offensively colored to Western eyes. An alternative style of rich margin also came in with the 16th cent., in colored papers sprinkled or elaborately figured with gold. Examples of the illumination are the same manuscripts as examples of the painting of the later period.

*Sculpture.* Of figure sculpture in the round the remains are negligible; literary descriptions of gold, silver, or bronze trees, horsemen, birds, lions, etc. in Islamic palaces indicate that metal was always its chief vehicle. Only one large piece remains from the whole medieval period: a bronze griffin (probably from Fatimid Egypt, 11th cent.) now in the Campo Santa of Pisa. Is is a work of inflated rotundity, all minor modelling suppressed in favor of energy curvature in the silhouette. Textile-like diaper-patterns and borders cover the purely decorative divisions of the surface. Lion-shaped incense-burners (Louvre; Met. Mus., N. Y.) and pumice-holders (the finest is in the Brummer coll. N. Y.), and other theriomorphic utensils (Hermitage Mus. Leningrad, esp. a cow nursing a calf) prove that the style was universal and long-continued in Islam. A few stone sculptures such as the lions of the Alhambra, the marble throne of the Gulistan Palace, Teheran, and the "nymphs" of the Chil Sutun Palace at Isfahan are far inferior in merit to the metal works. Decorative surface-carving is at its best in the Fatimid, Seljuq, and Mamluk periods.

*Minor arts.* Systematic description of the minor arts of Islamic peoples is not here feasible; nor is it desirable, since in many regions and for long ages they remained folk-arts, like the rugs of Turkestan, only specifically 'if at all affected by the true Islamic style. Some minor arts are of great beauty: Egyptian and Persian bookbindings; Egyptian marble water-vessels; wooden doors, panels, coffers, and furnishings, carved in medieval Turkestan, Persia, and Egypt, or painted in Safavid Persia and Ottoman Syria; the carved ivories (caskets, writing-cases, etc.) of the Cordovan Caliphate (Louvre, V. and A., Hispanic Society of New York) and later (Pamplona Cathedral, Burgos Mus., Arch. Mus. of Madrid); the intarsia furniture and bibelots produced in Syria and Egypt and, with the additional ingredient of metal, in a very characteristic form in 18th cent. Shiraz; Syrian glass of the early Islamic period and Persian glass of the 18th and 19th cents.; Moghul jewelry and early Qajar enamel on gold; Persian lacquered *papier-maché* and wood (notably a Safavid box in the Berlin SM. and the common pen-boxes with exquisite floral decoration of the 18th cent.); astrolabes in all periods; gold-inlaid steel weapons and implements made in Persia, Turkey, and Northwest India from the 16th to the 18th cents.

Perhaps less beautiful, but important to their users by the preciousness of their materials, are such objects as the Fatimid wheel-cut rock-crystal vessels (ewer of Caliph al-Aziz at St. Mark's, Venice; crystals in the Ksthist, Mus. Vienna ,the Louvre, the Rijksmus., Amsterdam); the rare pieces of early gold and silver (gold vessel of Bakhtiyar, Freer gall. Washington; Alp Arslan tray at Boston M.F.A.; 12th cent. gold wine-cup in the B.M.); the Ortukid enamelled bowl in the Landesmuseum of Innsbruck; the opulent Persian, Turkish, and Indian gold services in the Gulistan, Teheran; the Hermitage, Leningrad; the Moscow Museum; the Topqapi Saray, Istanbul.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

But there are two classes of artifacts profoundly expressive of the characteristic spirit of Islamic culture. The first may be subsumed under that group of arts which were, for limited periods only, sufficiently important to enlist the service of first-rate calligraphy, the recognized fine art: it includes seal-cutting, damascened metalwork from the 12th to the 15th cent., Syrian enamelled glass of the 13th and 14th cents., and ceramics in the Eastern Caliphate lands from the 10th to the 14th cents. The second class is the textiles and carpets of the whole Islamic period. Although it would seem that the capacity to weave expressive textiles arrives with the maturity of cultures, Islam supervened upon an already mature culture, in which architecture, the most significant of the arts, used textiles as an essential organ; and their importance was kept up by a general feature of Islamic sovereignty, the customary giving of robes of honor by way of reward, compliment, and investiture. The importance of carpets is connected both with that nomadic or open-air habit of life which even the city-dwelling Arabs, Persians, and Turks have never entirely lost and with the value of the carpet as an image, felt by the Persians with their peculiar world-view and inconceivable to us with ours.

The appreciation of Islamic seals lies entirely beyond the range of Western connoisseurship; the most renowned master was perhaps Ahmad Beg of Mekka (late 16th cent.).

Metalwork of the early Islamic period elaborates that of Sasanian Persian and the Christian East (post-Sasanian jugs and shallow cups, Hermitage, Leningrad; ewer from the treasure of Marwan II and similar bird-spout ewers, Arab Mus. Cairo and Hermitage, Leningrad). The dissolution of subordinate relief and approach to final Islamic form is seen in a bronze hawk (Berlin SM.) and a bronze stag (Nat. Mus. Munich). The final form as expressed in the Pisa griffin (v. sup. under "Sculpture") remained alive principally in Persia, where birds, animals, fishes, and fruits of gold-inlaid steel show little decadence even in the 18th cent Isfahan work.

Meanwhile, the inlaying of the metal surface with other metals, known to Sasanian smiths, had undergone a curiously rapid exploitation in "damascening", which appears practically complete in the earliest dated piece, the "Bobrinsky" caldron made at Herat in 1163 in the Hermitage, Leningrad. The bronze body of this vessel appears dissolved in the fine-spun figural and calligraphic decoration of inlaid silver and copper plates. This ambiguity of aspect is characteristic of all the great damascened vessels (late 12th cent. candlestick, Gulistan, Teheran; ewer of 1232, B.M.; basin made in Mosul for Badr al-Din Lulu, 1233-59, S. Bibl., Munich; basin for Najm al-Din Ayyub of Syria, Arenberg coll. Brussels; "Baptistere de S. Louis", Louvre; canteen with Christian subjects, Freer Gall., Washington; candlesticks, braziers, ewers, basins, of the early Mamluk period in the Ar. Mus. Cairo, the Met. Mus. New York, the B.M. and V. and A., London, Louvre, Berlin SM., etc.).

The same magical ambiguity of appearance was recognized (as Hariri's 18th. Assembly indicates) and prized in glass-ware (a Muslim traveller at Aleppo states that "when a man has gone into the Glass Market there he can hardly make up his mind to go away"). Blown vessels of grayish or honey-colored glass were painted with powdered glass of red, green, blue, and opaque white and gilded. Refiring fixed and fused the decoration, which rendered the vessels almost equally pervious to and reflective of light. Bottles, tall cups, standing bowls, and lamps were the usual forms. Aleppo was the principal seat of manufacture, and the period of greatest perfection extended from the late XIII to the middle XIV century. The only large collections are in the Ar. Mus. Cairo and the Met. Mus., New York (other fine examples; Freer Gall. Washington, V. and A. London, Louvre, St. Stephen's at Vienna.)

POTTERY. To the taste for the marvelous and mysterious so clearly evinced in the finest metal- and glass-wares rather than to the vulgar or orthodox imitation of gold and silver by which it has been very often and very naively explained we must attribute the development of the most characteristic of Muslim ceramic wares: **luster.** It seems that luster wares were first extensively made in Abbasid Mesopotamia, along with cobalt-painted white wares, imitations of T'ang splashed wares, and other significant early types (for the very earliest Islamic wares have nothing Islamic about them except their often disputable dates). Yellow, green, and brown luster designs were painted on an opaque tin-enamel ground. The subtle variations of tone in the material are not fully exploited in the bold designs of most early Mesopotamian pieces (griffin plate and dish with nursing camel, Louvre; jar, Art Inst. of Chicago), nor in the Fatimid lusters of the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

succeeding period (Louvre; bowl with tree full of birds, Cote coll., Lyons), nor in the large dishes and fantastically moulded jars of Western Islam (Alhambra vase, Granada).

In Persia from the 12th to the 14th cents. luster was made at Rayy, at Nishapur, and probably elsewhere, the finest wares being manufactured at **Kashan**, especially in the early 13th cent.. Words cannot describe the intimate and dreamy enchantment of the best Kashan pieces (*mihrab* from the Maydan mosque of Kashan, Berlin SM.; Eumorfopoulos bowl of 1210 in the B.M.; Havemeyer plate, New York; Huntsman bowl in the Kelekian collection, V and A.; smaller pieces in the Boston M.F.A.). For *mihrabs*, which were frequently executed in this technique at this period, very strong blue inscriptions appear to establish the Revealed Word as an apparition floating before the impalpable luster surface. Later Kashan lusters show Mongol motifs and degenerate drawing. Rayy lusters, though very freely drawn, are essentially cruder. Ruby- and gold-toned luster was used again by Safavid potters.

Another ware sometimes graced with superb calligraphy is a creamy pottery with brown slip and tomato-red bole designs made in East Iran about the 10th cent. Only two large pieces are known (Kann plate, Louvre; Schroeder bowl, Boston M.F.A.; fragments in Berlin SM.; "provincial" variants from the Nishapur excavations in Met Mus. New York).

Although there is reason to believe that the great Kashan potters made both luster and other types of ware, the more perfunctory even where equally skilful execution of inscriptions upon some exceptional pieces of underglaze painted pottery (reticulated jug from Macy coll. Met. Mus. New York; tile with Shahnama scene, Boston M.F.A.) prove that less importance was attached to them; on the less elaborate pieces the "writing" is often an illiterate imitation of letter-forms. Three ceramic types have remained characteristic of Islamic lands to today: blue-glazed wares, sometimes moulded; blue-glazed wares with black underglaze painted designs; and clear-glazed wares with underglaze painting in blue, black, and occasionally other colors. Of the first type an exceptional masterpiece is a turquoise-glazed lion, over two feet high, in the Kevorkian coll. New York; noble jars in this color were made at Raqqa. Of the other two types the finest pieces appear to have been made at Kashan (examples in all important colls.). A luxury ware of great gaiety is the ***minai*** overglaze painted pottery, with representations in Seljuq style of courts, picnics, horse-races, and incidents from romances. The most interesting piece is a huge plate with a picture of a siege, which even in its incomplete state has about seventy figures (Kelekian coll. New York). A similar ware with low relief and gilding is the most sumptuous of Persian ceramic types (bowl with lovers, Boston M.F.A.; horseman bowl, Met. Mus. New York; Edsel Ford coll., Detroit; harpy bowl, B.M.).

The so-called **Sultanabad and Sultania wares** of Mongol Persia, with animals, phoenixes, revellers, and cavaliers reserved against leafy thickets of Chinese foliation-motifs often in low relief, generally in grayish tonalities, are sometimes of great beauty ("Running Buck" bowl, Dumbarton Oaks [Georgetown], Washington).

Numerous other types of pottery express, though less eloquently, the singularly lyrical spirit of Persia in that age of fire and sword. The **Seljuq ceramics** of the immediately preceding period included a sgraffito ware with animal designs often of great strength, probably made chiefly in Western Iran (so-called "gabri" ware: examples in all important colls). The only original **Mamluk ware** is a coarse armorial style of pottery in similar technique.

But nearly all the eastern types enumerated were exported to and imitated in the East Mediterranean Islamic lands; the animal-drawing of some Mesopotamian underglaze-painted wares (associated with Raqqa) has a unique "heraldic" haughtiness of aspect. These Mediterranean lands preserved some late-classical formal qualities, and show a liking for flanged shapes (blue and gold albarello with spiral flange, Godman coll., Horsham, England).

In Persia the Timurids and their successors preferred imported Chinese pottery, so that although some 16th cent. Persian monochromes and lusters have a characteristic charm, most of the typical Safavid imitations and adaptations of Chinese models, and the late wares called Kubacha, Gombroon, etc. are of comparatively small artistic significance.

One more group of Islamic potteries ranks with the great types by its vitality and the importance which the quality of its calligraphy proves (blue-and-white inscribed bowl, B.M.): the **Ottoman wares** (formerly called "Damascus" or "Rhodian") believed to have been made principally at Isnik (Nicea), and

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

at their finest in the middle and late 16th cent. Blue-and-white, or cobalt-blue, copper-green and either tomato-red bole or manganese violet are the normal colors. Tulips, hyacinths, carnations, pomegranates and the other typical elements of contemporary Ottoman decoration, as well as lateen-rigged ships used as a repeat-spray, are drawn on the bottles, jugs, bowls, plates, and tankards as well as the tile-revetments of Isnik pottery with irresistible boldness, and occasionally with a marked poetical feeling (broken plate in the Boston M.F.A.; jug with Dutch mounting of 1580, V. and A., London).

TEXTILES. The history of Muhammadan textiles does not exist and cannot be summarized. No agreement exists among authorities either as to the provenance of many of the more important monuments or as to what associations of pieces are permissible.

Important textile-producing regions were early conquered by the Muslim Arabs. At least two types of splendid weaving were prized: tapestries of wool and sometimes of silk upon linen, and figured silks. Egypt especially produced tapestries, often figured with Christian subjects, to adorn linen garments with rich stripes or medallions.

Figured silks were made in China during the Han period (B.C. 206- A.D. 220). Raw materials for silk-weaving were exported thence for Western manufacture, and appear to have been first and principally woven into figured textiles in East Mediterranean lands (Syria? Egypt?) from the 4th cent. Justinian (6th cent.) established seri-culture in the Empire and textile factories at his capital. His contemporary Khusraw I of Persia appears to have interrupted the passage-trade of silk through his empire and may have established factories for figured silks. It seems probable that China, Iran, and Byzantium all produced silks in a Sasanian style of pattern; these grandiose stuffs, with beasts or monsters, paired or single, in medallions, are often considered the most noble textiles ever woven (Peacock-tail-monster or Senmurv stuffs in the Mus. d. Arts Dec., Paris, and V. and A., London; similar silk in Cooper Union Mus., New York).

Continuation of this style was the principal factor in the first three Islamic centuries ("sudarium of St. Columba and St. Loup", Sens Cathedral; lion silk in the Vatican; excavated fragments from Tun Huang). One of the most gorgeous monuments of Abbasid luxury is a silk-and-gold embroidery with peacocks and other birds, beasts, and monsters in roundels (Boston M.F.A.). But Islam itself contributed a characteristic variant of style: auspicious inscriptions, Koranic or Caliphal, often on bands alternating with bands, figured with birds, beasts, and flowers. The oldest textile which can with certainty be associated with Muslim ownership is a band-design silk with an embroidered inscription datable between 684 and 750 (V. and A. London). Such Egyptian pieces as a silk tapestry on linen with the name of al-Hakim (V. and A.) and an apparently Spanish piece (the "Veil of Hisham" at the R. Acad. Hist., Madrid) are comparable products of the Imperial Caliphal style.

Fine silk tapestries with Kufic and, later, round-hand inscriptions were woven in **Fatimid** and **Ayyubid Egypt** (Boston M.F.A.). The mantle of Roger II used as the Coronation robe of the Holy Roman Emperors is an embroidery in Fatimid style apparently made by Muslim workmen in Palermo in 1133 (Schatzkammer, Vienna). The finest "**Mamluk**" stuffs appear to have been imported from China; they attest the extraordinarily careful adaptation to Muslim tastes of Chinese manufacture for export in the Middle Ages ("Nasir" brocade with addorsed falcons, Marienkirche, Danzig; probably the silk from the tomb of Cangrande, Verona).

Curious stuffs (which have been associated with Sicily) were woven displaying bands of color woven in independently of the design. Sicilian stuffs were less esteemed than those of Spain, but satisfactory differentiation of the styles is not possible (silk with checker of entrelacs and addorsed griffins, V. and A. London; double-headed eagle silk, Kstgew. Mus. Berlin and Cooper Union, New York; 13th cent. mantle of Infante Don Felipe, Boston M.F.A. and Arch. Mus. Madrid).

It is notable that the Shahnama, written in Eastern Persia in about 1000 A.D., refers frequently to brocades: they are always "Chinese" or "Ruman" (Byzantine). A many-colored silk-and-cotton stuff called 'Attabi was woven at Baghdad, and perhaps striped silks were woven in Khuzistan. The famous "St. Josse" piece (Louvre) with confronted elephants, a border of camels, formalized ornamental stripes, and a Kufic inscription in the name of a 10th cent. Khurasan amir, may be an example of the silks known to have been produced in the Zarafshan valley of West Turkistan.

The silks in so-called **Seljuq** style, in a limited color-range, and often in two contrasted colors, are less spacious in design

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

than the earlier Islamic textiles. They sometimes employ very small-scale ornamental patterns (silk with winged lions and birds, V. and A. London; "Tomb-cover" and blue-and-red silk with guilloche in roundels, Text. Mus. of D.C.; double-headed eagle silk, Dumbarton Oaks, Washington). It is not known where such pieces were made.

The **Mongol** and **Timurid** rulers of Persia appear to have used mainly imported Chinese silks. Under the early **Safavids** European and Turkish velvets and brocades appear to have shared the favor of the rich, until the Veneto-Turkish wars choked off the traffic. But about the middle of the century it seems certain that precious textiles were being produced in Persia itself; the principal centers were Kashan and Yazd, old weaving towns. Strongly contrasted color, often based on crimson-and-white opposition, and a close dependence of design upon contemporary miniature-painting and illumination mark the earlier brocades and velvets. Ghiyath is a name found upon many of the finest pieces of the period. (Ghiyath's Layla and Manun silk, Boston M.F.A.; "Iskandar and the Dragon" brocade coat, Mus. Moscow; velvet of similar design, Met. Mus. New York; yellow-ground cup-bearer silk, Met. New York, and V. and A. London; hunting velvet from the top of a tent, Boston M.F.A.) Under Shah Abbas I (1587-1629) the capital, Isfahan, became a chief center of all arts and crafts. Brocades and gilt velvets were woven, sometimes with figure-subjects (lovers, cup-bearers, hunters), and sometimes with flowers in a new and less formal style. The colors are different: although it is hazardous to speak of stuffs which may have once been far more vivid, it seems that oranges, pinks, yellow-greens, etc. may have been combined in harmonies of saturation to give a peculiar "glow" to the stuffs of this period (Dated silk of 1599-1600, Met. Mus. New York; velvet brocade in Riza Abbasi style, Art Inst. of Chicago and V. and A. London; velvet brocade with flowers, rocks, and butterflies, silver brocade with doves, ducks, and roses, carpet-design velvet formerly in the Saxon royal coll., all now in the Met. Mus. New York; pieces in the Benaki Mus. Athens; coat in green and gold on pink, and silver brocade with jasmines, carnations, lilies and sunflowers, both in V. and A. London; velvet with Madonna, Correr Mus., Venice). The spacing of the sprays in many of the loveliest of the less elaborate brocades, the prevalence of a rectangular type of spray, and some characteristic color-combinations suggest that these may have been woven to replace or to surpass Indian textiles.

In India Muhammadan weaving was either modification or continuation of ancient Indian techniques or, in the 17th cent., emulation of Persian methods such as silk velvet-weaving (rug-design velvet, Blumenthal coll. New York) or brocades, often exceptionally rich in gold thread.

In Turkey the old Ruman style was continued by the Seljuq conquerors ("Kaikobad" gold and silk stuff with confronted lions in roundels, Text. Mus. Lyons). In the 15th or early 16th cent. a definite **Ottoman** or Turkish style arose. Pieces of the earlier 16th cent. show already the characteristic ogival trellises and diapers and the normal hyacinths, tulips, and pomegranates of Turkish decoration (green-ground silk no. 1356. 1887, V. and A., London; gold brocade coat with undulating stems, Met. Mus. New York; stuffs in Boston M.F.A.). In one well-known type of velvets for hangings, with few colors and bold designs, there is a certain strength or energy of curvature which is unique (red-and-silver or red-and-gold stuffs generally with pomegranate design, in all great collections of textiles or of Islamic art).

CARPETS. Both pile and tapestry rugs were woven; but all rugs of the first artistic importance are pile rugs, except for the tapestry weaving of gold and silver threads in certain luxurious **Safavid** and related rugs. Three types of knot occur: a knot round a single warp-thread characteristic of the oldest Central Asian and of Spanish rugs, the **Ghiordes** or **Turkish knot** in which two ends of yarn emerge between two encircled warp-threads, and the **Sehna** or **Persian knot** in which the two ends emerge between and outside (to left or right) respectively of the warp threads. The number of dyes was limited in the classic period: for red, madder and *kirmiz;* for blue, indigo; for yellow, Persian berries and turmeric; for brown, catechu; for black, logwood with iron. Double-dipping supplied secondaries.

The earliest recovered pile-rugs are fragments from Lou-Lan, Tun-Huang, and Antinoe in Egypt; the latter show imitations of mosaic design. A few fragments of the **Fatimid** period with Kufic inscriptions (Mus. Ar., Cairo; Text. Mus. of D. C., Washington) and some archaic carpets from the mosques of Konia and Bayshahr (Mus. of Turk. and Isl. Art, Istanbul) with simple geometric and "debased Kufic" designs indicate the medieval

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

style. This style was continued by the **Mamluks** and by the **Ottomans** in Egypt, under whom were produced the so-called "Damascus" rugs (silk rug, State Mus. Vienna; Met. Mus. New York).

A curious rug in the Berlin SM. displays a reduction to primitive knotting technique of a Chinese representation of the strife between the Dragon and the Phoenix; it is datable in the mid-15th cent. by its resemblance to a rug in a Sienese fresco of 1440-44. The so-called "Holbein" rugs such as that in the City Art Mus. of St. Louis, with geometrical designs in square fields or star and cross patterns, are sufficiently like representations in both Persian and Italian 15th cent. paintings to justify the belief that these were the typical rugs of Eastern Islam; they may have been woven both in Persia and in Anatolia, where the Persian art of the later Mongol period was admired. Or the Persian courts may have imported Anatolian rugs.

Late in the 15th cent. a new style of carpet first appears in Persian miniatures, adorned with curvilinear compartments, medallions, stars, and arabesques. The type has been called **Ushaq** after the great weaving town of that name, and its direct descendants (called **"Smyrna" rugs**) were woven in Anatolia as late as the 18th cent. The finest examples are in the V. and A., London; dated rugs which may be English copies (1584 and 1585) are in the possession of the Duke of Buccleuch.

Even if the analogy of the Ushaqs be held grounds for attributing the "Holbeins" to Anatolia, there is no doubt that in the early 16th cent. at latest the Persians began to weave what are considered the most wonderful rugs ever made. **Safavid rugs** are generally classified iconographically: as medallion carpets (with designs similar to illuminations and the more conventional bookbindings), as hunting carpets (with scenes of the chase), as animal carpets (similar to the last, but without human figures), as vase carpets (with exceptionally grandiose complex flowers spaced over a trellis of which some stems generally spring from vases), and as garden carpets (in which gardens are represented more or less in plan, with rectangular flower-beds, canals, pools, and trees). Many carpets combine two types. Shah Tahmasp himself designed carpets, and it is almost certain that his greatest painters and illuminators also did so. Several of the very finest are dated: two medallion carpets from the Ardabil shrine (1539) by Maqsud of Kashan, V. and A. London, and Duveen coll., New York; hunting carpet (1542 or 1522) by Ghiyath al-Din of Jam, Poldi-Pezzoli Mus., Milan; floral carpet (1656) by Mu'min, son of Qutb al-Din of Mahun, Mus. Sarajevo; silk carpet with flowers and trees (1671) by Ni'mat Allah of Jawshaqan from the tomb of Shah 'Abbas II. Amongst the finest undated Safavid carpets are a medallion rug in the Mus. des Gobelins; an animal medallion rug in the Mus. des Arts Dec., Paris; the "Coronation Carpet" in the Mackay coll. New York; a compartment rug (Yerkes coll.), Met. Mus., New York; an animal rug in the Ottoman Mus. Istanbul; a vase carpet in the V. and A.; a fragmentary vase-carpet with immense flowers in the Berlin SM.; a white-ground vase-carpet at Vienna SM.; a vase-carpet (former Lichnowsky) in the Altman coll. New York; a garden carpet formerly in the Figdor coll. Vienna. **Silk rugs**, often enriched with gold and silver thread, apparently made for royal use and royal gifts (especially to foreign rulers), were made during the 16th and 17th cents. Only three large 16th cent. examples are known; the Imperial Hunting Rug in Vienna, the Maurice Rothschild hunting rug, Paris, and a rug in the royal coll. at Stockholm. In the 17th cent. Persian looms produced a new type in these precious materials, in the same rather "Indian" color harmonies as some contemporary brocades, and generally with a very *mouvementé* design with long acanthus-like leaves. These silk rugs (called ***Polonaise***) may have been woven principally at Jawshaqan near Isfahan. What are often considered typical **"Herat" rugs** may be provincial or village versions of these designs in wool. Olearius (1637) reports Herat as a principal center of rug-manufacture.

The lands of the **Ottoman** sultans had long produced carpets, as we have seen (Armenian carpets were preferred even in Umayyad times). In the Caucasus and neighboring regions strongly geometrical forms give typical rugs an extremely archaic appearance. Reductions to this style of Safavid medallion and compartment rugs resulted in the so-called **Armenian Dragon-carpets**, made from the 16th to the 18th cents. (once thought to be far older). Fine examples are in the V. and A. and the Berlin SM.; a piece dated 1689 is in the G. H. Myers coll., Washington.

Other versions of **Safavid** rugs in the period of Safavid cultural prestige (16th-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

17th cents.), probably made in Western Anatolia and Istanbul, incorporate the typical hyacinths, tulips, and carnations of contemporary Ottoman decoration. More distinctive are the **prayer-rugs**, with clear niche-shaped fields, often between columns and sometimes with the representation of a mosque-lamp. The field is generally red or green. Early examples are comparatively rare (Mus. des Arts Dec., Paris; Ballard coll. in the Met. Mus. New York), but the type was multiplied in the common 17th, 18th and 19th cent. prayer rugs of Ghiordes, of Kula (with more ornament in the field), of Ladik (with "arrowheads" below the niches), and of Bergama (miscalled "Transylvanian" or "Siebenbuerger", with compartment borders and often floral fields).

Indian carpets of a specifically Islamic character were probably not made before the introduction by Akbar in the later 16th cent. of weaving on the Persian model, and probably at first by Persian workmen, at Lahore, Fathpur, and Agra. A magnificent rug in the Met. Mus. of New York gives an idea of the early style: a certain profusion and intimacy wholly Indian seems to inform the assemblage of the elements of an animal rug of Persian type. A rug at the Boston M.F.A. (early 17th cent.) with Indian interior and hunting scenes, beasts, monsters, and landscape is closer to contemporary painting than any surviving Persian rug. Other famous Indian rugs are in the Vienna Industrial Mus. and in the possession of the Girdlers' Company, London the latter was made at Lahore before 1634). Certain Indian rugs have in their borders vertically arranged, botanically drawn flowers, characteristic of Moghul album-margins (Met. Mus. New York). As *tours de force,* though not as works of art, some Moghul carpets surpass their Persian models: a silk fragment in the Met. Mus. has 2552 knots to the square inch.

CHIEF COLLECTIONS OF ISLAMIC ART, all partially published in periodical or cataloque form:

**isocephaly** (Greek fm. *isos* + *kephale,* equal—head). A style of composition in the visual arts in which the acting persons are arranged in such a way that they are of the same height; a manner of representation mainly pertaining to the Classical period of Greek art.

—L.L.

**itajime** (Jap.). The dyeing of fabrics by an unusual method, in which the fabric is clamped tightly between two thin boards with perforated designs; when the dye is applied it seeps in only through the perforations. Used in the *Suiko* Era, c.600 A.D. Ancient name, *Kyokechi.*

—J.A.M.

**ITALIAN ART.** Probably no country has played a greater role than Italy in the formation of the ideals of art in Western Europe and the highest expression of human endeavor in architecture, sculpture, and painting. The art of the Early Christian Church like all art, pagan or Christian alike, in the period of the disintegration of the Roman Empire is not, properly speaking, Italian at all, but belongs to the universal phenomenon of Late Antique art (q.v.). From the 6th to the 10th cents. there was an emergence of classical and oriental elements generally described as Byzantine art (q.v.). The monuments of Justinian in Ravenna and the later church of St. Mark's in Venice are eloquent proof of the extent of Byzantine influence in Italy.

*The Romanesque Period.* (*10th-13th cents. A. D.*). ARCHITECTURE. The first truly Italian art of the Middle Ages makes its appearance in the Romanesque (q.v.) period, roughly from the 10th to the 13th centuries A.D. As might be expected in a period distinguished by the rise of the great free communes in northern Italy, art found its greatest expression in monuments of civic and religious pride. The churches of Lombardy are marked by their massive construction, and by their barbaric decoration recalling the ingenuity of Lombard jewelry. The building was entirely in the hands of the masonic guilds, the Magistri Comacini (q.v.), who were instrumental in spreading the Lombard style to the furthest reaches of the Pilgrimage roads in Spain. North Italian architects developed a form of the ribbed groin vault which is often regarded as the precursor of Gothic construction. The best example is in the famous church of Sant' Ambrogio in Milan. The architects at this period retained the traditional basilican form; as in later periods of Italian architecture the spaciousness of the interior is enhanced by the retention of the classical square bay. The principal decorative features were the corbel table and the use of open and engaged colonnades on the exterior.

The architecture of Tuscany was exemplified most nobly by the celebrated group at Pisa comprising the Baptistery, Cathedral, and the famous Leaning Tower. These buildings are in no sense marked by the structural solidity and logic of Lombard Romanesque. A wooden roof spans the aisled basilica interior. Exterior and interior of the cathedral are almost extravagantly decorated with varicolored marbles. The church, the Baptistery, and the tower are harmonized by an identical decorative scheme; continuous colonnades of slender pillars girdle the buildings in successive stories which increase the feeling of height and unite the group in a decorative whole. It has even been suggested that the Leaning Tower was a deliberate caprice of the architect Boscatus.

The Romanesque cathedrals of Sicily, notably the great shrine of Monreale, and Cefalú, reflect the tastes of the various races that contributed to Sicilian civilization of the 12th cent. Saracenic interlaces twine on towers of Norman inspiration. The interior of Monreale is ablaze with mosaics of Byzantine inspiration. In the wonderful interior of the Palatine chapel in Palermo Islamic vaults and arches are resplendent with the Greek mosaicist's art.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

PAINTING. The Romanesque painting of Italy as exemplified principally by certain 11th cent. frescoes at Sant' Angelo in Formis shows a revivification of the Byzantine heritage that already foreshadows the tremendous moving power of Italian religious art in centuries yet to come. What can only be described as a Latin vigor, seen in the almost brutal heaviness of line and brilliance of color, makes these decorations rank among the greatest religious paintings of the time.

SCULPTURE. Italian sculpture of the 12th and 13th cents. is a part of that international style of art, with mixed borrowings from the classic, the Byzantine, and the barbarian traditions, which flourished all over Europe in the Romanesque period. Certain sculptors, such as the Lombards Guglielmus and Benedetto Antelami, are truly Italian in their crude attempts to reveal the beauty and sturdiness of the human form in a realistic manner quite apart from the patterns and formulae of their contemporaries.

*The Gothic Period. (13th-15th cents. A.D.)*

ARCHITECTURE. The Gothic period in Italy from the 13th to the 15th cents., marked by the greatest spiritual expression in the arts, is in many respects the prelude to the Renaissance. The Gothic architecture of central Italy has in reality very little to do with true Gothic construction. Churches like the Duomo at Florence retain the old basilican plan. The architects continue to show a marked predilection for the square bay, a feature which in itself mitigated against the attainment of those effects of loftiness so distinctive of the French cathedrals. Again, for climatic reasons, and even more because of the ineradicable classical heritage, the Italians were unwilling, and for structural reasons unable, to eliminate the walls of the building. Except for a few isolated instances where French masons were employed, the Italian Gothic churches can be recognized as such only by the employment of pointed arches which on no occasion were utilized to the same effect as in France. The exteriors, particularly the façades, were given extraordinary decorative treatment, mosaics and colored marbles contributing to the gorgeousness of the effect.

The domestic buildings of the period, as exemplified by the Palazzo Vecchio in Florence, are fortress-like structures distinguished by their heavy rustication and, in contrast to this massiveness, by that final symbol of civic pride, the slender campanile.

PAINTING. It was in the field of painting that the first true signs of Italian greatness became manifest in the 14th cent. In the works of the Sienese painters Duccio di Buoninsegna (active 1285-1311) and Simone Martini (active 1315-1344) we may note a gradual emancipation from the Byzantine tradition. Duccio's work, although based on Byzantine formulae, is marked by an effectiveness of dramatic presentation that is typically Italian. Simone, greatest of the mystic painters, is almost Oriental in his delineation of the supernal forms. The real giant of the period was the Florentine, Giotto di Bondone (1266-1336), sometimes called the father of modern painting. His study of Antique and Early Christian works of art combined in him to produce the first truly monumental painting since Classical times. His figures are imbued with an enormous solidity and gravity that give them the aspect of being hewn from granite. The very simplicity of his style contributes to Giotto's direct and masterly presentation of the Christian drama. Giotto's figures by their impersonality have the universal power of persons in Greek tragedy. They are a kind of super-humanity of Giotto's own imagining. Giotto was the first to immortalize the legend of St. Francis and to imbue the pictorial story of the Passion of Christ with a sober pathos that is the more moving for the simplicity of its eloquence. The Lorenzetti (d. 1348) of Siena combined Giotto's form with a dramatic intensity that is completely Gothic.

SCULPTURE. The sculptural equivalents of Giotto are the marble-workers of the Pisani family. Niccolò Pisano (ca. 1205?-1278?) received his training in the workshops of Capua where a school of classical sculpture was sponsored by Frederick II. His reliefs of the New Testament which decorate the pulpits of Siena and Pisa have the same massiveness of form and restrained drama found in Giotto's frescoes. Giovanni Pisano's (ca. 1250—ca. 1317) figures are tormented and wasted forms writhing in a frenzied movement that suggest that same imminent exhaustion found in the flamboyant art of northern Europe. We may see here, however, an emotional expressiveness through the violent contortions of the human form, contortions which in Northern art are merely affected posturings.

*The Renaissance. (15th and 16th cents. A.D.)* The Renaissance, as the name implies, is a period of awakening and, by popular

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

definition, the rebirth of the classical spirit. This was no sudden sporadic flowering but the fruit of a long period of development. The Renaissance interest in man and the realities of this world can already be discerned in the art of the late Middle Ages. We may perhaps suppose that the mediaeval idea that all things in our ken are reflections of the beauty of God fostered a crude realism in art that needed only the scientific spirit of the Renaissance to bring it to perfection. Again, the 15th and 16th cents. only emphasized the attachment to the classical past that had never been entirely lost. Perhaps the most concise explanation of the phenomenon known as the Renaissance is that whereas in the Middle Ages God was the center of the cosmic Machine, in the Renaissance Man became a cosmos in himself, and all things in life and art alike were measured by the human rather than the divine standard. Man saw Beauty reflected in himself rather than in the ineffable Godhead. Indeed in the Italian art of the 15th and 16th cents. it is the beauty and dignity of humanity in that age and all other ages that is the keynote of creative endeavor. In this period as never before nature in all its manifestations was explored. Architecture became a work of human pride, its magnificence and taste intended to reflect the magnificence and taste of the human builder. The medieval cathedral was a symbol of God; the Renaissance palace a symbol of Man. In the 15th cent. Science brought to fulfillment and began the ruin of Western art. The beginning of self-conscious expression in the Renaissance was ultimately to lead to the emptiness and meaningless expression of modern art.

Painting of the Renaissance. It would be difficult to nominate any one painter as the founder of Renaissance painting in Italy. We can only single out certain individual artists who were the first to apply the principles of the new scientific vision and scientific experimentation which replaced the certainty of religious belief and formulae of the Middle Ages. The first astonishing monument of Renaissance painting was the cycle of frescoes painted by Masaccio (1401-1428) in the Brancacci chapel of the Carmelite church in Florence. His figures retain the statuesque bulk of Giotto's forms, but for the first time they appear as living things in a defined space and atmosphere. No painter ever succeeded in imbuing his forms with the dignity of man more completely than Masaccio. In the great painting of the *Tribute Money* the heroic group of Christ and the apostles is set off against a landscape suggestive of the Arno valley and composed for the first time according to the laws of atmospheric perspective. Masaccio was one of the first painters to represent the diminution of color-intensity in shadow and to abandon the mediaeval convention whereby in modelling colors were presented with their highest intensity in deepest shadow. Masaccio's contemporary, the beloved Fra Angelico (1387-1455), was essentially a mediaeval painter who did, however, make certain innovations in landscape and in the painting of figures and architecture in proper rather than symbolical scale. Uccello (1397-1457), whose dreams were inspired by the researches of the mathematician Manetti, seemed to paint largely for the sake of demonstrating his theories of scientific perspective. His battle-pieces are like strange fairy-lands with cubistic wooden figures and splendid details of military gear arranged in attitudes calculated to lead the eye into the depths of the panel. Another pioneer was Antonio Pollaiuolo (1433-1498) whose interest lay in the exploration of the structure of the human body. His representation of battling men and gods are more than anatomical *écorchés*: they are drawn with a real suggestion of struggle and action that communicates itself to the spectator. The painter who perhaps more than any other exemplifies the nostalgic longing of the Renaissance for the classical past and who best reflects the Platonic visions of the Medicean court was Sandro Botticelli (1447-1510). Botticelli's mythology is scientific insofar as it is based on the investigations of contemporary humanists, but it has a poetic and mystical quality that is strangely reminiscent of the medieval. Although thoroughly aware of the scientific innovations of the day, Botticelli was not interested in the exploration of the realm of Science. He developed a technique of line drawing that invests its figures with wraith-like insubstantiality and the movement of flowers stirring in the wind. The strange translucent pallor of his people, their very insubstantiality, suggest the longing of the neo-Platonic soul for the ineffable and eternal beauty of the Divine, a longing which Botticelli expressed in pagan and Christian allegories alike. Botticelli was in every way a Renaissance Christian personality moved alike by the Latin poetry of Politian and the fanatic Christian eloquence of Savonarola,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

If one were to pick one individual representative of the Renaissance mind in all its facets, one would turn to Leonardo da Vinci (1452-1519). This great Florentine genius was primarily a scientist and inventor. His experiments in aeronautics and military engineering were among his many magnificent failures. In a way painting was simply part of that nature and universal science whose secrets he sought to plumb. Leonardo was interested in recording both the physical action and the psychological states of the human animal in much the same way as he studied the movement of water and the growth of plants. His famous *Last Supper* is a kind of tour de force attempting to register the reactions of the group of apostles to Christ's accusation of betrayal. They are real persons and at the same time personifications created from his sketches and memories of hundreds of real models. The *Mona Lisa* again is as much a portrait of an enigmatic introspective personality as a replica of a personage of flesh and blood. The scientist Leonardo brought many innovations to painting, notably the use of deep chiaroscuro to render most effectively the subtleties of facial expression and bodily form. As a draughtsman who was able to suggest the articulation and inner movement of the human fabric Leonardo has never been surpassed.

The last and greatest of the Renaissance giants was Michelangelo Buonarroti (1475-1564). Michelangelo considered himself primarily a sculptor. His schooling was in the studio of a conservative Florentine painter and in the classical collection of the Medici family. Michelangelo presents the curious phenomenon of a medieval Christian in a pagan world. The dynamic tormented movement of his giant forms is a reflection of the struggle and unhappiness of the man himself. The decoration of the ceiling of the Sistine Chapel is a vast allegory of the Fall and Redemption inspired by the pages of St. Jerome. The *Last Judgment* was a kind of giant poster intended to advertise to Michelangelo's lost and sinful generation that, as Dante stated, eventual redemption awaited even sinners through the cleansing torments of Limbo and Purgatory. Michelangelo has always been admired for the accuracy and power of his drawing of the human nude; like no other artist he was able to use the human form to express the greatest depths of suffering and the highest exaltation of the human soul. In the hands of his imitators the same bodies became simply huge posturing mannequins devoid of meaning.

The 15th cent. painters of **Umbria** are renowned chiefly for the development of landscape and the suggestion of spatial effects. These features can be noted in the work of Perugino (ca. 1450-1523), whose work is distinguished also for its almost pietistic sentimentality. In earlier centuries Umbria had always been the home of saints and mystics. A much greater figure and entirely lacking in the popular sentimentality of Perugino was Piero della Francesca (ca. 1416-1492). His figures have the statuesque simplicity and grandeur of Egyptian sculpture. They are for this impersonality tremendously heroic, and move in landscapes austerely furnished and bathed in the cold blue Umbrian air. Piero was one of the first painters to suggest the presence of outdoor light as a factor in the picture enhancing form and color alike. Luca Signorelli (1441-1523) might well be described as the greatest of the Early Renaissance anatomists. His researches into the structure of the human frame enabled him to paint with tremendous conviction the armies of naked figures that move in the scenes of the last days of the world in his great eschatological drama painted in the San Brizio chapel at Orvieto. The work of Luca Signorelli is but one illustration of how the Renaissance artist, like the masters of that antiquity which they sought to recapture, used the nude human form as a vehicle for powerful emotional expression. His work illustrates, too, how Science, in this case the science of anatomy, was opening up new vistas to the artist. In the medieval period anatomy was a thing prescribed by formulae, designed to produce a divine proportion. In the Renaissance it was based not on systems of *a priori* divine perfection, but on the knowledge gained in the dissection of cadavers.

The last great painter of Umbria was Raphael Sanzio (1483-1520), the pupil of Perugino. In the early years of his career Raphael showed himself no more than a simple improvisor on the sentimental themes of his teacher. His real greatness is to be measured by those works which he produced under Papal patronage in Rome. His masterpieces are the series of frescoes decorating the Stanza della Segnatura in the Vatican. The *School of Athens* and the *Disputà* are not only extremely profound and recondite symbols of pagan and Christian metaphysics, but masterpieces in the sugges-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

tion of tangible space and depth on a flat surface. Even the sentimental *Sistine Madonna* is extremely moving in the subtle suggestion of the Madonna's floating down toward the spectator out of the infinite sky that forms an aureole behind her.

A north Italian collector and passionate admirer of antiquity was Andrea Mantegna (1431-1506). He filled his religious panels with *membra disiecta* of Roman monuments, not so much as symbols of the decay of the pagan world, but because he loved the cold perfection of classical forms. Mantegna is notable also for his startling experiments with perspective and fore-shortening. He was one of the first artists to suggest that the space of the painting was a continuation of actual space.

If the humanism of Florence was one of the mind, the humanism of Venice was dedicated to the senses. Whereas painters like Botticelli recorded in classical allegory the intellectual triumphs of the Medici, the painters of Venice even in religious painting were concerned with recording the color and pageantry of this semi-Oriental capital on the Adriatic. The paintings of Gentile Bellini (1426-1507), although religious in subject matter, are most notable for his figuring in an almost anecdotal style the costumes and architectural appearance of the city in his time. Giovanni Bellini (1428-1516), the most famous member of the Bellini family, was the first to develop that splendor of color which is the special glory of the masters of the High Renaissance. He inaugurated the technique of painting in transparent oil glazes, a method practiced extensively by the Flemings and supposedly introduced to Venice by the south Italian master Antonello da Messina. Giovanni Bellini is able to impart an almost Flemish pathos to his painting of the *Dead Christ in the Tomb*. His many representations of the *Madonna and Child* fall just short of being likenesses of contemporary beauties. In the backgrounds of his pictures Giovanni Bellini paints some of the most distinguished landscapes of the Renaissance. The blue hills of the Trentino, the square and simple white houses on distant slopes are bathed in a really convincing impression of light and atmosphere. Giovanni Bellini's pupil was short-lived, but brilliant, Giorgione (1478-1510). His famous reclining *Venus* in the Dresden Gallery is the sensualist Venetian counterpart of the intellectual nudes of the Florentine painters. His representation of the nubile fullness and provocative softness of the feminine form is the complete expression of Venetian humanism that sought perfection in physical form and not in a neo-Platonic dream of loveliness. The composition with the figure and a screen of trees, half concealing the background and leading the eye to an exploration of the distance, is one that was used over and over again by the famous Titian (1477-1576). This long-lived and exceedingly prolific master was like all the men of Venice totally lacking in those intellectual interests and qualities which dominated the lives and painting of the artists of Florence and Rome. Titian, like all the Venetians, was entirely a painter of the physical beauty of man and nature. He developed to its fullest extent the Venetian technique of painting in transparent glazes so that his figures and landscapes alike appear transfigured with a magnificent golden light. It must be pointed out that neither Titian nor for that matter any master of the period ever attempted to reproduce directly the actual effect of outdoor light. He simply suggested its brilliance and warmth by formulae developed in the studio. Titian's color was probably the most beautiful of any artist of the Italian Renaissance. His famous *Bacchus and Ariadne* is a superb color poem of the warmth of the Mediterranean sun, a Renaissance pagan's vision of beauty when the world was young. Titian's most famous pupil was Tintoretto (1518-1594) who was chiefly notable for his dramatic innovations in the composition and especially the lighting of religious scenes. His famous painting of the *Last Supper* in San Rocco is built on the dramatic diagonal of the table receding into the background. The multiple forms that throng this Venetian feasting scene are dramatically illuminated by the light emanating from the person of Christ. Tintoretto gains much of his dramatic effect by the violent juxtaposition of lights and darks in his paintings. The last of the Venetian Renaissance masters was Veronese (1528-1588), a painter of religious scenes that were criticized even in his time for their irreverent qualities. The *Wedding at Cana* is a Venetian feast laid in a Palladian hall, painted with great breadth and richness and totally lacking in spirituality.

Corregio, (1489-1534), the famous master of Parma, continued Mantegna's experiments in perspective and foreshortening in his decoration of the dome of the cathedral of Parma, a fresco that prophesies the elaborate representations of celestial space by the painters of the baroque period. He preferred human beauty of an exotic, alluring type. Correggio

had his own technique of painting flesh in melting silver tones that makes both his religious and pagan subjects the most sensuous ever painted.

ARCHITECTURE OF THE RENAISSANCE. The architecture of the Renaissance was as much as painting a reflection of the material and spiritual attitude of the day. Building, perhaps even more than painting, was affected by the re-discovery of antiquity. The architects of the early 15th cent. were content with a timid application of classical detail to structures still essentially medieval. Only later did the architects turn to embodying the proportions and structure of antique prototypes into their buildings. This was an intelligent borrowing and not, as in the work of the neo-classic movement, a slavish reproduction of classical models. As Botticelli in his *Birth of Venus* was in a way competing with the lost original by Apelles, so the architect of the Renaissance sought to create a style based on the ancients but suited to modern usage and surpassing the work of the classical masters. Architects like Brunelleschi (1377-1446) were not only designers but great engineers. Brunelleschi's famous dome of the cathedral of Florence was essentially mediaeval in form but thoroughly Renaissance in the magnitude of the undertaking and the application of certain principles deprived from the structure of the Pantheon. The heavily rusticated facades of the Florentine palaces recall the exterior of the medieval Palazzo Vecchio; classical details appear in the windows of the famous Medici-Riccardi palace, its colonnaded courtyard with arches resting on Corinthian columns is a direct borrowing of a famous Roman device. Brunelleschi's Pazzi chapel is Rennaissance mainly in the application of pediments and Corinthian pilasters and columns. This rather illiterate use of classical detail is replaced by a much more scholarly, one might say humanist, approach in the buildings of Alberti (1404-1427). To the first-hand craftsman's knowledge which Brunelleschi had gained by studying the stones of Rome Alberti added a profound knowledge of the principles and aesthetics of Roman architecture. His façade for the church of San Francisco at Rimini is an improvisation on the theme of the Roman triumphal arch The same motif was enlarged to a gigantic scale at the church of Sant' Andrea at Mantua. The interior of this building uses the massive barrel vaults of the Roman bath.

The great epic of Italian architecture in the Renaissance was the rebuilding of the basilica of St. Peter's in Rome. From the time that the Early Christian Church was demolished by Pope Julius II practically every well-known Florentine and Roman architecture submitted plans for the magnificent edifice in the very center of the Christian world. Michelangelo, more than any other man, made his architectural personality felt in the present structure. According to his original plan the church was to be a Greek cross in form with four massive piers to support the lofty and magnificent dome. Although both the plan of the church and the great cupola itself were modified by architects of the baroque period, whatever is magnificent in the construction is due to Michelangelo's conception. The effect of spaciousness that would have been present had the Greek cross plan been retained was spoiled by the lengthening of the nave by the 17th cent. architect Maderna; this baroque nave also spoils the effect of the dome by partially concealing it from the east. The cupola is the final development in dome construction; the result, like Brunelleschi's Florentine dome, is in two shells and is raised on a lofty drum. Throughout the church the giant order is employed. So massive is the structure that, especially from its west end, it appears like a great granite plateau on which the dome has been raised. The one great criticism of the building is that no sense of scale is provided to judge its vast dimensions.

One of the architects who preceded Michelangelo in the work on St. Peter's was Donato Bramante (1444-1514) of Milan. Although his early work in that city is in the florid picturesque style of Lombardy, his buildings in Rome reveal a mature and distinctly classical style. The famous Tempietto consists of an almost archeological copy of the Temple of Vesta surmounted by a ribbed Rennaissance dome. The building is characteristic of that sobriety and dignity that distinguish all the buildings in the Eternal City in the High Renaissance. Michelangelo's famous group of buildings on the Capitoline Hill is perhaps most notable as the first example of assymetrical planning on a central axis. The lateral buildings of the group are aligned so as to direct attention to the central member and to provide a feeling of spacious expansiveness that was to reach its highest development in the baroque period. One of the most influential and classic of the Renaissance architects was the Venetian Palladio (1518-1580). He studied Vitruvius and the writings of Al-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

berti. His style came to influence profoundly the buildings of Thomas Jefferson.

SCULPTURE OF THE RENAISSANCE. The history of Italian sculpture in the Renaissance in many ways parallels the developments seen in painting. Ghiberti (1378-1455), author of the famous *Doors of Paradise* of the Florentine Baptistery, was in many respects still a medieval artist. The suggestions of actual depth and atmospheric perspective in his reliefs of the *Creation* have their parallel in Masaccio's frescoes in the Brancacci chapel. The sturdy forms of Jacopo della Quercia (1371-1438) prophesy Michelangelo in his sensitive understanding of the beauty of articulation in the human form. The great sculptural genius of the Florentine Renaissance was Donatello (1386-1466) who in his youth had gone with Brunelleschi to study the antiquities of Rome. His famous bronze David was indeed the first free-standing nude figure to have been made since the Classical period. Donatello's greatness lies not only in the ease with which he was able to suggest the animal beauty and movement of human beings but in his ability to suggest the existence of thought and life behind the masks of his statues. Donatello seems to have been profoundly affected by the realism of Roman portraiture but his heads are more than a mere topographical recording of the physical envelope. They appear imbued with thought and in the true interpretation of the "speaking likeness" seem ready to become articulate. Donatello's many representations of the haggard John the Baptist are saved from being mere veristic recordings of emaciated anatomy by the extraordinary spirituality of the pathetic features. Donatello was a true Renaissance artist in his interest in showing an action not only physical but mental. An artist famed mostly for his many sentimental renderings of the Madonna and Child was Luca della Robbia (1400-1482). The glazed terra cotta medium he employed was developed to its highest point by this sculptor and his successors. His greatest monument is perhaps the *Singing Gallery* in Florence, beautiful in its recording of the healthy Tuscan childhood. One of Donatello's most powerful monuments was his equestrian statue of the Condottiere Gattamelata. Its conception was based in part at least on the antique equestrian group of Marcus Aurelius. It remained for Andrea Verrochio (1435-1488) to produce the greatest equestrian statue of the Renaissance, the memorial to Colleoni, which may well stand for the eternal personification of the cruelty and power of the professional warrior.

Italian sculpture of the High Renaissance finds its final perfection in the work of the universal genius Michelangelo. Sculpture was his favorite medium, and it was in marble that he achieved his greatest triumphs and failures. His inability to complete the vast sepulchre commissioned by Julius II was the great tragedy of his life, and yet the fragments of this uncompleted monument are among the greatest wrought by his chisel. The *Moses* may be taken as an example of that terrible and awe-inspiring power with which Michelangelo was able to invest his statues, partly by their giant scale and partly by Michelangelo's development of the principle of contraposto whereby the body is twisted on its axis, suggesting emphathetically a kind of struggle physical as well as spiritual within the fabric of the stone being. The *Bound Slave* again reveals a relaxation, an exhaustion that is a kind of personification of the futility of existence. A great deal of obscure and probably unjustified symbolism has been read into Michelangelo's statues, especially the Herculean forms on the tombs of the Medici. It is certainly true, however, that these vast forms seem to reveal a weariness as though from an inner struggle that parallels the struggle between Christian and pagan in the soul of Michelangelo himself.

*Mannerism.* The early 16th cent. in Italy saw the florescence of a style generally defined as *mannerism* (q.v.), not necessarily because the artists worked in the manner of their predecessors but because their style was mannered in the sense of being eccentric and distinctly self-conscious. The figures of painters like Parmigianini and Pontormo are enormously attenuated and of a languid grace strangely out of keeping with the giant bodies with which they have been endowed. Fugitive shades of lavender, rose, and lemon-yellow lend a strangely cold and twilight atmosphere. It is almost as if the artist were catering to the strange exotic tastes of the exhausted generation in which he lived. The same fondness for attenuation and mannered grace may be seen in the sculpture of Benvenuto Cellini (1500-1571). In a sense it was a search for novelty through perversion in a world in which there was nothing left to say. The work of the mannerists shows the first self-conscious straining for effect through distortion of the normal proportions. In the field of portraiture men like Bronzino and Parmigianino were masters. Their over-elegant style

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

was admirably suited for interpreting the over-sophisticated personalities who were a part of the decay of the Renaissance world.

*The 17th and 18th Cents.* Just as it is impossible to fix an exact date for the beginning of the Renaissance, in like manner would it be foolhardy to single out an exact year for the inauguration of the baroque epoch. Just as Giotto already anticipated many of the concepts of the Renaissance, so it could be said that men like Michelangelo had already developed many of the concepts of the 17th cent. style.

The definition baroque has always been one of disparagement, implying floridity and lack of refinement. Certainly the baroque art of Italy is not classic: it lacks restraint, but it is as powerful and emotionally exciting as any form ever devised by human artists. In the art of the 17th cent. there is a strangely fluid and effective blending of mediums: sculpture becomes pictorial; painting, plastic; and architecture frequently becomes painterly and trembles with movement. This was an art for effect and effect alone.

Baroque art in Italy is first and foremost an art dedicated to the propagandizing of the Roman Catholic Church; that is, the new and powerful Church that emerged with the founding of the Jesuit order. It is an art of ostentation intended to surprise and move the emotions. It was intended to re-enforce the appeals made to the heart by the sermons of the Jesuit fathers.

BAROQUE SCULPTURE. One of the greatest of the Italian baroque artists was Gian Lorenzo Bernini (1598-1680) whose architecture and sculpture are in every way characteristic of the tastes of the period. Bernini's sculpture, as illustrated by his group of *Apollo and Daphne,* is a far cry from the almost frontal concept of statuary in the Renaissance period. It is specifically meant to be seen from all sides. The figures are no longer enclosed within themselves but definitely suggest that they are part of space in general: their realism, with the imitation of texture in marble, prepared the way for the makers of mortuary sculpture in modern Genoa. Bernini's famous *Ecstasy of St. Theresa* is not only a representation of a mystic experience in concrete, it has been said even Freudian, terms, but a new and pictorial and sculptural form in which the stage and spatial setting of the group are a part of the ensemble.

BAROQUE ARCHITECTURE. Bernini's architecture, too, is filled with devices intended to suggest a vast scale and expansiveness in space. This is particularly notable in his famous colonnades of St. Peter's which reach out like giant calipers to embrace the ancient square by their inclination from the basilica's facade artificially enhancing the feeling of space and distance. The architecture of the baroque, like the architecture of a stage, is built for effect. The interior of churches like Vignola's (1507-1573) Gesú in Rome eliminated the aisles in order to enhance the almost overpowering sense of expanding spaciousness, to concentrate attention on the pulpit, and to accommodate the large audiences of the Jesuit sermons. Stucco clouds and marble angels on the cornices lead the eye to a vast ceiling-painting of *Christ in Glory,* creating the illusion that the infinite reaches of Heaven itself open directly from God's temple on earth. It is not surprising that a material age which required such material concepts for its spiritual nature should have demanded a new magnificence for the physical world as well. No better illustration of this could be found than in the great villas that surround Rome and Naples: the Villa d'Este at Tivoli with endless picturesqueness of garden vistas and Caserta where the nightingales sing. In contrast to the façades of the Renaissance churches which might be described as closed and plastic in the non-projection of any salient elements, the exteriors of the baroque shrines of Rome are deliberately startling and pictorial. A staccato effect of light and shade is achieved by constructing the façade in a number of planes projecting one beyond the other. The violent breaking of entablatures, the employment of curve and counter-curve, sometimes, as in the fantastic edifices of Borromini, almost produce an effect of actual rippling movement in architecture. The effects are deliberately bizarre in what is really a kind of ecclesiastic opera scenery, intended by its very novelty and richness to advertise the power and richness of the new Church.

BAROQUE PAINTING. Painting, no less than architecture and sculpture, was intended to startle and move by direct appeal to the heart and senses. New techniques of realism came into being in the effort to interpret the Bible story in completely human terms. Caravaggio (1569-1608) of Naples devised a technique of violent chiaroscuro whereby the figures, usually in a dark setting, are illuminated as though by a spotlight to lend a new and dramatic violence to the interpretation of the martyrdoms and Gospel incidents which he pictures. The Eclectics, principally the members of the Carracci family in Rome,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

founded an academy and attempted by a formula intended to combine the features of the best Renaissance artists to produce a final perfection in painting. This search for a kind of philosopher's stone in art shows the strange exhaustion of the creative tradition in the 17th cent. It marks too the beginning of academic art which attempts by setting up such *a priori* standards to produce an art which *ipso facto* will be good. Appeal through cheap sentimentality which had been latent even in Renaissance art was developed as never before by such saccharine masters as Guido Reni. This magazine-cover type of religious art was enormously popular and greatly encouraged by the Church whose needs it suited so admirably.

If the baroque painters lack the intellectual stature of the humanist masters of the 15th and 16th cents., they excelled as the tastes of their times demanded, in the development of various aspects of realism, notably the effects of endless celestial perspective achieved by the painters of ceilings in the churches of Rome and Naples. Landscape, which in the Renaissance had been only a kind of timid stage setting, emerges as a separate form of art. We may see this in the rather classical landscapes of the Carracci, in the wilder aspects of nature pictured by the romantic Salvator Rosa, and finally in the architectural vistas by the 18th cent. Venetians, Canaletto and Guardi.

*The Neo-Classic Movement.* (*18th - 19th cents.*) It must not be supposed that the classical spirit or the taste for classical things was in any sense lost in the extravagance of the high baroque. Even the architecture of Bernini is classical in his continual employment of the classical orders and in its extreme severity. Indeed the attachment to the classical past which had lived on in Italian history for a thousand years after the fall of Rome was to enjoy one final moment of supremacy in the latter half of the 18th cent. This was in the so-called neo-classic movement that had its origin in Italy with the discovery of the ruins of Pompeii and Herculaneum. The sculptor Canova (1757-1822) was only one of many artists all over the world who sought to embody the dictates of the German archeologist Winkelmann that perfection in art was to be found only in an imitation of the "noble simplicity" and "quiet grandeaur" of the antique. This was the first regrettable instance in art history when artists sought inspiration neither in nature nor in their own spirits but in the imitation of the art of the past.

*Conclusion.* From the close of the 18th cent., the artistic supremacy in Italy gradually vanished, perhaps because of the disorder and exhaustion during the 19th cent. Except for imitations of the prevailing Parisian fashions no further original art was produced. In the 20th cent., esp. in the last fifteen years, conditions have hardly favored the growth of the creative spirit. One may mention only Chirico with his symbolic nightmare visions of classical fragments as the last of a great tradition. See Anderson, W. J., and Stratton, A., *Architecture of the Renaissance in Italy,* 1927; Brown, A., and Rankin, W., *A Short History of Italian Painting,* 1914; Fokker, T. **Italian notation.** See NOTATION.

**Italian porcelain.** See CERAMICS II.

**Italian style.** A style of art essentially different from Flemish art in that the emphasis was on the plastic effect of form and color while Flemish art emphasized a literal presentation of reality. Its influence permeated all of Europe during and after the Renaissance. —R.L.W.

**Italianizers.** A group of Flemish artists of the 16th and 17th cents. who travelled in Italy and imitated the Italian style. This influence created a fusion of the two styles. Some of the Italianizers were Jan Gossaert (Mabuse), Van Orley, Michael van Coxcyen, Lambert Lombard, Pieter de Kempenaer, Jan Massys and Frans Floris. The painters and others who worked in Rome called themselves "**Romanists.**" —R.L.W.

**ithyphallic** (Greek fm. *ithus* + *phallos*). A mode of representation in which male persons are shown in a state of sexual excitement. Frequent in the reproduction of Satyrs on Greek vases of the 5th cent. B.C. —L.L.

**itomaki** (Jap.). The cord wrapping of the handle of a sword.

**ivan.** (Ar.) An open-ended vault. See ISLAMIC ART; PERSIAN ART.

**ivory.** Widely used as a material for carving and, to some extent, as a support for paintings, ivory has been a material familiar to artists from ancient times. Strictly, the word indicates the tusk of an elephant, but practically those of the walrus, the hippopotamus, and other animals, some of them even from prehistoric remains, have been used. In substance and structure this material is a tooth formed out of phosphates and similar substances lying in layers deposited by the growth process. Unlike bone, it can be worked as soon as it is cut. —G.L.S.

**ivory black.** See bone black.

**ivory carving.** See EARLY CHRISTIAN ART.

**Ivory Coast art.** See AFRICAN NEGRO ART.

**ivory tusks.** See SYMBOLISM IN FAR EASTERN ART.

**ivy.** In classical art, especially Greek pottery, a decorative pattern in which heart shaped leaves are set on either side of the continuous stem line, either directly opposite each other or where the stem is slightly wavy, set to fill in the hollows. —L.T.S.

**Iwakurayama yaki** (Jap.). Pottery made in Yamashiro province.

**Izumo yaki** (Jap.). Pottery made in Izumo province.

**Jack of Diamonds group.** See RUSSIAN ARTS.

**jacket.** *Book.* The wrapper of a book from the publishers. Usually printed and decorated but sometimes unprinted, and also a transparent wrapper showing the cover design on the book itself.

**Jacobean.** The Jacobean style, a term derived from Jacobus, the Latin name for James I, who ruled England from 1603 to 1625.

The Jacobean manner was actually born during the last years of Elizabeth, when the Italian classicism imported by Henry VIII gave way before the rising baroque; but it was a German and Flemish baroque, full of bizarre effects and heavy forms. Among interior designers the period is sometimes known as the "**Age of Oak**"; generally it is typified by the most popular of its contributions to the development of furniture, the ponderous refectory table with bulbous legs. See ex libris; FURNITURE.

—P.C.B.

**Jacquard attachment.** Mechanism on a loom which selects the proper color. Its operation is controlled by a perforated record which resembles very much the record that is used for a player piano. —B.E.J.

**Jacquard loom.** Invented about 1800 and is now used in the making of Brussels and Wilton carpets.

**jade.** A mineral, ranging from white to black, used extensively in oriental art. For terms, see the following: *chang, ch'i, han, hsi pi, hu, huang, kuei, kuei pi, ku-pi, lung, pi, spinach green, sui, susan chi, ts'ung, and ya chang.* See also *Jade,* Berthold Laufer, Field Museum of Natural History, 1912; *Early Chinese Jade,* Una Pope-Hennessy, 1923.

—J.A.M.

**jamb.** The side of a window or door opening.

**jami.** (Ar.). A mosque. See ISLAMIC ART.

**JAPANESE ART.** *Pre-Buddhist Art.* The early cultural history of Japan is rather obscure but the few surviving examples of Pre-Buddhist art are of interest chiefly because they exhibit certain qualities peculiar to native Japanese art existing before the succession of waves of influence from the outside and reappearing after each wave has been absorbed. These characteristics, expressed in the *haniwa,* archaic clay grave figures, and *dôtaku,* bronze bells covered with engraving, have been described with the words, *heimei, meikai,* and *meiro,* suggesting a liking for simplicity and directness, cheerful ingenuousness, unclouded by philosophy.

The native style of architecture, *tenchi-kongen-miyazukuri,* was a primitive wooden building consisting of two posts set in the ground supporting a ridge-pole to each end of which were fastened two rafters which sloped to the ground. To these rafters a number of beams were tied horizontally to support a thatch which served for walls as well as roof. Later this whole structure was elevated by introducing four walls and a floor. Four early types of Shinto architecture based on this simple form were, *Taisha, Otori, Sumi-yoshi,* and *Shimmei.*

*Suiko Period (580-650).* In the 6th cent. Buddhism pushed its way through China and Korea and came to Japan and the art so intimately connected with it came also. The first Buddhist sculpture was sent over by the King

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

of Paiche in Korea. Korean art was then following the style of Northern Wei and this style developed rapidly in Japan during the reign of Empress Suiko. It was a formal art, sharp and rigid.

A large number of temple builders, painters, sculptors, tile makers, and other artisans came from Korea. Buddhist temples were built on a grand scale and what remains of these buildings eloquently speaks of the magnificence of the imported style.

*Hakuohô Period* (*650-720*). The Hakuoho was a transition period marking the gradual development of the intensely nationalistic art of the Tempyô. In the early part of the period there was increasing direct intercourse with China. Customs and manners, art and religion were industriously copied. Sculpture followed that of Sui and early T'ang in losing the Wei stiffness. It became more sensuous and three-dimensional, and toward the end of the period it began to develop independent characteristics, although the painting of this time remained faithful to its continental origin.

The court was established at Nara in 710 and the capital was laid out after the Chinese plan. The Imperial Palace buildings had roofs of green glazed tile and pillars painted red. The temples were painted with red oxide and the interior in full color, the peculiarity of the decoration of this period being the gradation of different shades of color, the result being known as *unsen*.

*Tempyô Period* (*720-810*). The art of this "blossom-time of Japanese civilization" reflects the virility and vitality of the times, a period of great political and religious ardor. The influence of China was still strong, for fixed canons of religious art came from there, but the native character predominated. There was a great output of sculpture. It was realistic and had a three-dimensional quality best expressed by the word *ryo* meaning "volume" but also suggesting solidity and an active rather than passive strength. They contain an inner force pressing outward, ready to overflow. The statues produced around the middle of the 8th cent. give an impression of animation and an open frankness which makes them pleasant as well as imposing. Toward the end of the period, however, they become heavy and the full curving flesh gets fat.

Beside the religious art realistic portrait statutes were made and grotesque masks used in *Gigaku*, a comic dance imported from the continent. These masks differed from Buddhist art in being wholly worldly and from the portrait statues in being unrealistic.

The materials used by the sculptors were, painted wood, lacquered wood, dry lacquer, hollow lacquer, paper mache, and some bronze and clay, and toward the end of the period woodcarving.

*Jogan Period* (*810-980*). This and the following period are often united and called **Heian**; it was another transitional time in which the vigorous Tempyo art declined and was replaced by the delicate and fragile Fujiwara. However there was a special influence of the time which had its effect on the art. This was the introduction of the religious sects of Shingon and Tendai. These esoteric sects, from one point of view may be called the sects of painting and sculpture. In Kobô Daishi's *List of Importations* it is said that "the inner meaning of the esoteric doctrine is different to put down in words but by the use of painting and sculpture it will be comprehended." The motivating spirit of these sects was an occultism that transcended realism and their painting and sculpture were consequently ideological and removed from realism. Certain characteristics were added that derived from southern India. Formalism set in; realism disappeared. In painting an expansive style of treatment was in favor, the figures drawn to such a size they fill the face of the picture and almost overflow its borders. A famous painter of the 9th cent. whose name still survives though none of his pictures do, is Kanaoka who founded the **Kose** school.

The esoteric sects also had a vital effect on religious architecture. Hitherto the temples had been built in cities and on level ground but now they came to be built on mountain tops, necessitating certain changes in the construction. The symmetrical arrangement was no longer possible and greater freedom was allowed in the design. A curve was given to both gable and roof.

*Fujiwara Period* (*983-1170*). This period is named after the Fujiwara family who intermarried with the Imperial clan and managed to monopolize all the high official positions of the government. The court was moved to Kyoto where amid wealthy and aristocratic circles, art and literature flourished. Elegance and refinement were carried to extremes and the art acquired a graceful and feminine beauty. It is sometimes called the period of decadent sentimentalism.

Chinese, heretofore the language of learning as Latin was once in Europe, gave way to the use of Japanese in literary expression and in the 10th cent. there were enough Japanese poems to be collected into a book. Poetry had long been a favorite form of expression. The poems were usually 17 or 31 syllables in length and arranged in a special way. They did not describe but suggested, the aim of the poet being to stimulate and then direct the imagination of the reader, trusting him to make the poem for himself. Sometimes they expressed a complete idea, other times a sigh of regret or an exclamation of joy.

Another form of literature popular at this time was the romantic novel, half historical, half legendary, idealistic tales of the heroes of medieval wars. The literature with few exceptions never reached the heights it did in the west, nor was there much of it. An interesting book, *Tale of Genji*, by Lady Murasaki gives a great many significant pictures of the manners and customs of the court life of this time.

The pictorial illustrations of these tales and verses was a very popular form of art. These were painted on scrolls which like the movies obtained their effect from a development of the subject corresponding to the flow of pictures. Paintings were also made on poem card size paper, ***uta-e,*** or poem-pictures. One of the esoteric sects used landscape screens in the religious ceremony and a technique of landscape painting developed, "piling up of mountains in many layers." The painting of this period was designated by the term ***yamato*** to indicate its essentially Japanese character.

The aristocrats built temples and mansions on an elaborate scale, developing a style known as ***shinden-zukuri*** which consisted of a number of rectangular buildings joined by long corridors, with a landscape garden on the south side containing a large pond with an island in it connected by bridges, one in front and the other in back, the front one enabling boats to pass under it. Such was also the plan adopted for palace architecture. The houses of the common people remained simple with thatched roofs.

*Kamakura Period (1170-1350).* Historically this was a period of reconstruction after the civil wars that ended the Fujiwara period. Minamoto no Yoritomo moved the government to Kamakura to preserve the Bakafu from the degenerating influence of the luxury of Kyôto, and his successors, the Hojo family, continued the tradition of soldierly simplicity for the rest of the period. The resulting spirit did not supersede the dreamy grandeur of Fujiwara all at once, but a new vigor and love of nature was injected.

Sculpture flourished under the genius of Unkei and his followers, it was full of strength and solidity and common sense, but later developed mannerisms and became overelaborate. Painting followed the same general lines though the influence of Sung is more clearly visible. ***Bugaku,*** a new operatic dance brought from China replaced the *Gigaku.* The masks were smaller and shallower than *Gigaku.*

The Zen sect of Buddhism brought to Japan from China spread among *samurai* and aristocrats and had a profound influence on all phases of Japanese life and art. This religion which combined soldierly virtues with a refined aestheticism promoted detachment from worldly desires and the cultivation of concentration, decision, and simplicity.

The Zen temples of Sung were reproduced in Japan and the style of these new buildings were called ***kara-yo,*** Chinese style, the older style which continued to exist from the previous period was named ***wa-yo,*** Japanese style; finally they merged into one and developed a mixed style. The *wa-yo* allowed great freedom in the planning of the temple and in the arrangement of the different buildings while the *kaya-yo* retained, as in the case of the Buddhistic architecture first introduced from China in the 7th cent., the symmetrical arrangement. It simplified the interior of the temple and at the same time added more decorative detail to the exterior, such as carving for the gable ends. A third style was the ***tenjiku-yo,*** or Indian style, which featured an elaborate system of bracketing.

The powerful war lords rivaled each other in building magnificent mansions for themselves thus giving stimulus to the development of painting, architecture, gardening, and the various branches of applied arts. ***Buke-zukuri*** was the style developed for the *samurai* class. It was customary for the *buke* style to surround the house with a ditch and fence. Instead of having many separate buildings as in the *shinden,* the *buke* had many rooms under one roof, or groups of roofs joined together.

*Ashikaga Period (1350-1570).* The Ashikaga clan abandoned Kamakura and Kyôto again became the political center. The simple ways of the *samurai* were forgotten but the popularity of Zen increased. The religio-philosophic principles laid down by that re-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

ligion for every form of art were assidiously cultivated. There arose a type of architecture based on the *shinden* and *buke,* called ***shoin-zukuri.*** This style introduced into the dwelling houses the ***tokonoma*** (an alcove for paintings and flowers), shelves on the wall for ornaments, sliding paper screens. The tea-ceremony, ***Cha-no-yu,*** developed into a fine art and a special form of architecture, ***chaseki,*** arose in connection with it. The *chaseki* was like a primitive hut in the middle of a forest. A tiny and simple room with no decoration other than a single painting or example of calligraphy, and a flower.

Also in regard to the tea-ceremony the art of the potter must be mentioned. In ceramics as in other branches of art the Chinese influence was great. Much of the porcelain of the kind usually exported, Imari, Satsuma, shows little of the refined taste of the Japanese found in the work of the potter. These artists allowed their personality and individuality to appear in their work. The bowls and jars made to be used in the tea-ceremony were not made for commercial purposes but to be loved and cherished for their beauty and the skill of the craftsman.

Another development of the aesthetic of this time was the *No* drama. These are religious or at least solemn and serious plays, inculcating Buddhist morals. They are played in skillfully carved masks suitable to the character portrayed and are chanted or intoned to a particular kind of musical accompaniment. Descriptive and explanatory passages being sung by some of the musicians. The dancers move through a series of stately posturings prescribed by tradition. The text is mainly in verse and filled with scholarly allusions which makes it difficult to understand. This was (and is) the theatre of the aristocrats, highly conventionalized and intellectual. They are short plays with only four or five characters and it is customary in one evening's performance to give five *No* and three short farces called ***Kyogen*** which ridicule everything.

A style of painting, a swift ink sketch in black and white line and wash, brought from China during Kamakura by Zen priests, ***suibokugwa,*** attained high development during this period. Nearly all of the early ***suibokugwa*** artists were Zen priests and the art kept its religious quality until about the end of the 15th cent. when the Chinese spirit left and then the paintings represented pure artistic enjoyment of the medium. The first of the great ***suibokugwa*** artists was Shûbun; he founded a line of painters, Jasoku, Bunsei, Oguri, Sotan, Gei-ami, Sôami, Nôami, Keishôki, and other masters. These belong to what later became known as the Chinese School or ***Kangwa.*** A greater artist Sesshû, the "ink-splash painter" formed a more personal style. He represented his own feelings rather than the quality of the landscape. His followers were Sesson and Shôkei.

Buddhist painting and sculpture by this time had fallen by the wayside. It had become either stylized and over-elaborate, or stylized and crude. The ***Yamato-e*** painters now represented by the ***Tosa School,*** continued but the refinement is gone. Kano, a new school founded during this period by Kanô Motonobu, the first to study both *Kangwa* and *Yamato-e,* gave a Japanese flavor to Chinese-style painting.

*Momoyama Period* (*1570-1630*). This time saw the consolidation of the states and there was a general reaction from the severity of Ashikaga. Momoyama art was extraordinarily gorgeous and brilliant. Things were done on a grand and ostentatious scale barely saved from vulgarity by the vigor of the artists. The latter had by now turned their attention completely toward men and things connected with daily life. One of the great contributions of the period were the beautiful six-fold screens the Kano artists painted by the hundreds to decorate the new castles and palaces. They chose as subject matter, flowers, animals, trees, seasonal landscapes, using the gold ground as clouds or space in an integral part of the design. Screens with clothes for their subject are known as ***tagasode-byoha,*** "Whose clothes? screens."

An outstanding individual artist, Kôyetsu, a distinguished painter, incomparable calligrapher, designer in wood, metal, and lacquer, together with his friend and follower Sôtatsu, founded a school intimately Japanese. Their art was a fusion of Tosa and Kanô. They started with an abstract design of related or opposed forms and melted natural form and color into it.

*Tokugawa Period* (*1630-1867*). The Tokugawa dictatorship which lasted over two centuries and a half was distinguished by the orderliness of the feudal system and the elaborate organization of the government. The social structure was necessarily founded upon a rigid distinction between the rulers and the ruled and this distinction was preserved by force and only so could it be preserved especially when the accumulation of wealth by the merchant class began to threaten the or-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

der. When at this time foreign intercourse was forbidden Japan was forced into a period of national isolation. Under such stagnant conditions the people could only elaborate what they had inherited from the previous ages. The painters produced by the now academic Kanô and Tosa schools engaged only upon refinement of their traditions and their work became nothing more than tedious repetition. Mausoleums and edifices were built in the old style overlaid with elaborate decoration until they became a crowded medley of carvings and pictures.

The evolution of the common dwelling house was now completed. Based on *chaseki* and *shoin* the houses developed so that the landscape gardens became an indispensable part of the home. Of one or two stories, a grey tile or thatched roof, the house is divided into rooms by sliding screens. Light is admitted by paper-covered lattice movable so as to throw the rooms and the garden into one. The aim was to bring man closer to nature and the art of the gardens was to conceal beauty in such a way that it might be discovered individually. ***Shibumi,*** "an unassuming quality in which refinement underlies a common-place appearance, appreciable only by a cultivated taste", was in demand.

One outstanding exception to the rule of solid conservatism was Korin whose refinement on tradition resulted in a daring and original decorative art. He followed in the path of Kôyetsu and Sôtatsu and produced a gorgeousness tempered by refined taste. He was a master of every branch of the decorative arts. His brother, Kenzan was also a fine painter but even more distinguished as a potter.

Matabei, who lived at the end of the 16th cent. and through the first half of the 17th, founded a kind of genre painting called ***ukiyo-e*** ("Floating World"), paintings of ordinary life. He originated the manner followed by the artists who produced the color prints more appreciated in the West than in Japan. Moronobu, in the latter half of the 17th cent. was the first of this school to produce prints, although in black only. His followers carried the process further. At first the black prints were touched by hand with a red pigment called *tan*; these ***tan-ye*** as such prints were called soon gave place to prints with fuller color. Then black lacquer was used to reinforce the moderately full palette in the hand-colored prints, these are known as ***urushi-ye.*** This was the final form of the hand-colored print. Kiyonobu produced the first sheets made wholly by printing and this was the method followed by the rest of the printmakers. He was also the first to design portraits of actors which remained one of the staple themes along with portraits of fashionable beauties, esp. courtesans.

All through the early part of the 18th cent. prints were made of increasing complexity until at last Harunobu pushed the printing process back to its furthest limits. To mention only a few of the printmakers, Kôryusai, Kiyonaga, made prints of great dignity and beauty, Shunshô and Sharaku, noted for their portraits of actors, Utamaro, whose absorbing theme was woman, Hokusai and Hiroshige captured on their landscapes the various moods of nature, Kuniyoshi and Kunisada were outstanding masters of figure design. At the close of the 18th cent. the character and quality of the woodcuts declined, cheap pigments were used and an attempt was made to reproduce paintings.

In late Tôkugawa an interest in the decorative colored style of later Ming gave inspiration to a number of painters, Bunchô, Rikurikio, Taigadô, Buson, Kwanzan, and others. The naturalistic movement produced such masters as Goshun, Ikyo, Ganku, and the most eminent of this school, Mori Sosen, painter of monkeys, deer, and other animals which he studied in their native forests. Jakuchû painted gorgeous cocks, hens, and fishes, while Soga Shohaku, another contemporary pursued an independent line and tried to recapture some of the spirit of the 15th cent.

*Meiji Period (1868-1912).* The restoration of power to the Emperor in 1868 marked a new opening to every outside influence, largely to the neglect of national heritage. In the first two decades it seemed as if the national tradition, everything inherited, were to be wiped out, but soon a reaction set in and the cultural heritage was revived. Occidental manners in many phases of life and art had been adopted and an attempt was made to reconcile these with the Japanese culture but the result has not been a happy one. **Japanese prints.** See PRINTS AND PRINT PROCESSES.

**japanning.** See FURNITURE.

**Japonism.** *Japonisme, Japonaiserie,* used by French writers of the second part of the 19th cent. to cover the whole complex of interest in the art of Japan. A society of Japanophiles established ca. 1900 in Paris called themselves *Japonisantes*. Today the use of the term Japonism has been limited to the influence of Japanese art, esp. that of the Japanese colour print upon the graphic arts, painting, crafts and interior design of Europe and America during the 2d part of the 19th cent. and the 1st decade of the 20th.

The *chinoiserie* of the 17th and 18th cents. (q.v.), terminated by neo-classicism survived only sporadically in the crafts of the Biedermeier style in Germany and Austria and fused in England with neo-Gothicism during the Victorian era. It was through the channels of the French "realistic" graphic arts that East Asiatic influence reasserted itself, but this time almost exclusively limited to Japanese art,—more specifically to that of the Japanese print of the Ukiyo-é school, a popular branch of Japanese painting during the Tokugawa period (1603-1867), in very low esteem, among the Japanese conoisseurs themselves.

Dates most frequently mentioned in connection with the history of Japonism are: 1856, 1862, 1867. In 1856 the French etcher, Félix Braquemond (1833-1917), "discovered" Hokusai's "Mangwa", used as packing material in a parcel of porcelain sent from Japan in the shop of his printer Delâtre. In the year 1862 the movement spread in Paris to circles of etchers, painters and collectors among them: the etchers Bracquemond and Legros; the painters Manet, Monet and Degas; the writers Edmond and Jules de Goncourt, Champfleury, Zola, Burty and Duret; the editor and collector Charpentier, the Count Cammondo, names all well known in the movements of French realism and impressionism. These Frenchmen were joined by the Belgian painter Alfred Stevens, the English painter James Tissot, and the American Whistler as habitués of the *"Porte Chinoise"* in the rue de Rivoli, a curio shop run by Mr. and Madame de Soye who had lived for a while in Japan. All of them, esp. the Goncourts and Whistler, were more or less collectors of East Asiatic art, chiefly Japanese.

In 1867, the year of the first Japanese department organized by the Japanese Government at the Parisian World Fair, came the foundation of *"La Société Japonaise du Jinglar"*—named after a French wine—a club of Japonophiles, who met in Sèvres in the house of Solon, the director of the porcelain manufactory of this place. Among others belonged Solon, Braquemond—who introduced Japanese decor to Sèvres porcelain—Zacharie Astruc, the manysided friend of Manet, the writer Burty, and the painter Fantin-La-Tour. Claims of having been the discoverers of the Japanese print were also put in by the brothers de Goncourt who in their "Journals" as early as 1866 became champions of Japanese art, which they collected on a large scale and which Edmond made popular through his books on *Outamaro, le peintre des maisons vertes* (1891) and *Hokusai* (1896).

The influence of the Japanese print was naturally felt first in the graphic arts, where it coincided with the revival of etching in France (*Société des Aquafortistes* founded in 1862). Braquemond, the key figure in this movement, advised both Manet and Degas in their attempts at etching; the not too numerous graphic work of these artists shows in the quality of line, in the flat treatment of areas, in the asymmetrical, casual arrangement of the composition and in the way in which foreground figures are "cut off" and only partly visible,—a marked Japanese influence. Yet there were in the arts of these men no obvious ethnological borrowings as, e.g. in the prints of Paul Rivière who like Whistler signed with a Japanese signet. Degas' American pupil Mary Cassat gave to a series of 10 coloured engravings one print of (1891) the title *Attempted Imitation of a Japanese Print.* Whistler's etchings are proof of the application of what he called "the Japanese theory of drawing", while in his early oils done between 1862 and 1864 Japanese setting and costumes occur; e.g., in his *La princesse du pays de la porcelaine.*

In England, tendencies towards Japonism allied themselves with the pre-Raphaelite movement—both brothers Rossetti were collectors of Japanese prints. Beardsley's sophisticated black and white art is an interesting fusion of pre-Raphaelitism, Greek vase painting, French rococo and very decisively, the Japanese print.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Book illustration and ornamentation, esp. in England, Germany, Austria, Belgium, and the Scandinavian countries, becomes one of the chief vehicles for the dissemination of Japanese motives and compositional principles. The illustrated art magazines such as the English *Studio* (founded 1893), the German *Pan* (1895), *Jugend* (1896), *Simplicissimus* (1897), *Deutsche Kunst und Dekoration* (1897), the Austrian *Ver Sacrum* (1898), the French *Art et Décoration* and *L'Art Décoratif* (1897), all of which were in the front line of the struggle for a new style independent from historical prototypes (known as *art nouveau* in Belgium, France and England, *Jugend Stil* in Germany, "style liberty" in Italy) testify to the great importance given to the Japanese print and crafts as an inspiration.

Of even more lasting influence and of greater social significance is the role played by the Japanese print in the evolution of the poster. Toulouse-Lautrec's lithographic coloured posters (the earliest from 1891-2, among them one for the cabaret, *Divan Japonais*), book jackets and music covers adjust Japanese decorative principles, colour scheme and line quality to Western taste and needs.

Most of the aforementioned artists, esp. Manet, Degas, Whistler, Toulouse-Lautrec, show Japanese influence also in their water colors and oils. Yet the influence of Japan upon the painting of the impressionists, such as Monet, Renoir, Pissarro and Sisley, although undeniable, has been exaggerated, since the two-dimensional space conception of East Asiatic art and the stress upon light and atmosphere in impressionist painting, creating there a strong three-dimensional effect, are mutually exclusive.

In the paintings of the post-impressionists, such as van Gogh and Gauguin, where tendencies toward two-dimensionality and line quality are most marked, the influence of the Japanese colourprint is most evident. It finds expression also in the numerous references to Japanese art in the writings of these men; in the letters of van Gogh to his brother Theo and to his friend the painter, Emil Bernard; in Gauguin's book *Avant et Après*. In the art and theory of Gauguin it is already part of his interest in primitive art. It is this "primitivism" which succeeded Japonism as "exotic" influence upon the arts of the West.

The very considerable influence of Japan on the crafts and interior design in Europe and America is an integral part of that movement for the revival of the handicrafts which we trace back to William Morris and for which no general name yet exists. It continued in the style referred to above as *art nouveau, Jugend Stil,* style liberty. It is of great significance that L. Liberty, the founder of the craft shops which bear his name in England and the continent, as well as S. Bing, whose shop "Art Nouveau" in the Rue de Provence in Paris (founded 1896) gave their names to the movement, both started as dealers of Japanese prints. In the early designs of the Belgian Henry van de Velde, the Germans and Austrians Behrens, Eckmann, Endell, Moser, Obrist, Pankok and Bruno Paul, motifs from Japanese prints have been applied. Most of these men were in the beginning of their careers more designers of ornament (for tapestries and wall papers, for instance) than architects. Therefore, the Japanese exterior architecture, and most of all the Japanese interior with its emphasis on empty space—"the domestication of infinity" —was not of the same interest to them as the decorative accessories, of ceramic, lacquerwork, iron sword guards, flower arrangement, etc. One of the first to value the qualities of the Japanese layout of house and garden in its dynamic freedom and natural adaptation to the surrounding landscape was Frank Lloyd Wright who, before he had an opportunity to travel and build in Japan (1915-22),—especially in his domestic architecture during the nineties and the first decade of this century—was pursuing similar aims. The U. S. A. had in Ernest Fenollosa (the American, Lafcadio Hearn), John La Farge (*An Artist's Letters from Japan*, 1886) and Henry Adams (*Letters from Japan*, 1886) men with fine understanding for the values of East Asiatic art who did not merely measure them with the yardstick of western aesthetics.

Among the crafts Japanese influence was most strongly felt in ceramics, glass and metalwork where the objects in the Japanese departments of the Parisian World Fairs of 1867 and 1878, and further, the enthusiasm of private collectors and museums had made numerous artists and laymen familiar with the skill and taste of the Eastern craftsman. Especially the coarser Japanese ware of the "raku" type with its thick and irregularly flowing glazes, ornamented as well as unornamented, inspired the Western potter.

Outstanding in French ceramics were Bigot, Chaplet, Damouse, Delaherche; in the U. S. A : Mrs. A. Robineau in Syracuse (1865-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

1929), Prof. Ch. F. Binns (1857-1934), in New York, Mrs. Mary Chase Stratton in her Pawabic Pottery, Detroit, all of whom appreciated and studied Japanese ceramics. In Denmark the porcelain of Royal Kopenhagen shows in its decor the marked influence of such Japanese artists as Korin.

Lalique (Paris) and Gallé (Nancy), the outstanding French craftsmen in glass, used Japanese decoration for their cut glass, although the technique of multi-coloured, deeply cut glass seems to have been inspired by the so-called Chinese "snuff bottles" of the later periods.

To this group of French craftsmen belong also the American, Charles L. Tiffany and his son Louis C. who in their designs for jewelry and other crafts employ the florid curvilinear character of Japanese decoration.

John La Farge in some of his stained glass windows, e.g., in the "Peacock Window" follows somewhat the example of Whistler's famous "Peacock Room" (Washington, Freer Coll.) done for the house of his patron Leyland on 49 Prince's Gate, London in 1867—one of the earliest although not too successful attempts to design a whole room with its furniture, pictures and decorative accessories in the East Asiatic—or better—pseudo-East Asiatic style.

The echo of the 19th cent. interest in Japan in European literature and music ranges from the serious to the burlesque, from Pierre Loti's *Madame Chrysanthème* (1887) which enthused van Gogh and furnished ideas for the libretto of Puccini's successful opera *Madame Butterfly* to Gilbert and Sullivan's *Mikado* (1885). **jazz.** A style of dance music, played by a smaller or larger ensemble, the band, which began in the U. S. A. at the time of World War I and has since spread over the whole world. This style is primarily one of *performance.* It referred originally to improvisatory circumscriptions, particularly rhythmical ones, of pre-given, generally rather simple compositions. These improvisations were done either by individual players or by the whole ensemble. In commercial practice, improvisation has more and more disappeared. It has been replaced by the jazz arrangement, by the sometimes very sophisticated adaptation of the basic tunes by specialists, either as stock arrangements for general use or as special arrangements for particular bands. The basic materials of these arrangements, however, are, with few exceptions, either older established hit tunes or the current ones of the day, "plugged" and exploited by a small group of publishers. Very often, these tunes as such have very little to do with jazz style proper. They may be treated in many different ways. An exception is only the so-called "rhythm numbers" which are from the very beginning conceived in terms of jazz performance.

The most obvious characteristic of jazz is the prevalence of the syncope which may be expanded in such a way that the syncopations form a kind of new symmetry or "pseudo-measures" among themselves. Even the simplest cake-walk rhythm may be interpreted in terms of pseudo-measures; i.e., 3/16 + 3/16 + 2/16, within a 2/4 measure. What distinguishes jazz, however, are not these syncopations as such,—which are the equivalent of the element of rhythmical improvisation—but rather their relation to the ground beats which throughout the piece are rigidly maintained in a machine-like manner against the syncopated improvisations. These ground beats are either actually marked (in the bass drum part and by *pizzicati* in the double bass part) or they are implicitly understood and observed. The idea of jazz as well as its understanding are bound up with the simultaneous appearance of something inexorably regular and of something that breaks away from this regularity—in a stumbling manner, as it were—only to ever come back

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

to safe rhythmical ground again. One might say that jazz subjects the performer as well as the listener to an incessant test: how far his musical consciousness is capable of snapping with the fingers at the norm without ever abandoning it seriously. This double character is peculiar to jazz in all its elements. Even the sound which "vocalizes" the instruments, making the mechanical musical elements subjectively vibrate without ever breaking the command of these elements, manifests the same intention.

Historically, the jazz style was engendered partly by the folk music of American Negroes (spirituals and blues), partly by syncopated American ditties which can be traced back to the earlier part of the 19th cent. Since Winthrop Sargeant published his careful and learned book, *Jazz Hot and Hybrid,* the Negro origins of jazz are clarified and identified in all technical details. At the same time, however, this book repudiated the belief in the primitive spontaneity of present-day jazz.

With regard to the final establishment of the style, the introduction of step dance, defining the ground beats in terms of marching, must have been of the utmost importance. The organization of the jazz band is akin to that of the military band. The sentimental features of jazz expression are derived from *salon* music; its particular harmonic stimuli coming from musical impressionism. The idea of jazz in a somewhat broader sense, is most intimately related to that of the eccentric clown and the American slapstick and film comedy. All the latter aspects of jazz, however, have so far been much less stressed by musicology than the folk art aspects. Yet, as far as the basic structure of melody, harmony, and metrics is concerned, jazz stands absolutely on the level of traditional dance music which it has embellished but has not essentially changed. Its innovations belong mainly to the sphere of rhythmical and instrumental tricks. In particular, the instrumental techniques of the clarinet, trumpet, saxophone, trombone, and percussion instruments are indebted to jazz.

All the musical essentials of jazz could already be found in ragtime, before World War I. Ragtime, however, was primarily limited to the piano. The first jazz fad was brought about by the appearance of the first jazz bands. At that time also, the name "jazz" was introduced. Since then the basic idea and the rules of the game have settled. Hence, it is difficult to speak of a "history" of jazz in the proper sense. The changes it undergoes are comparable rather to those which fashions in clothes undergo. They are engendered chiefly by the desire to stimulate consumption of what remains ever the same by constantly changing its mode of occurrence; each such change being rigorously stylized and made as obligatory as possible.

With the increasing technological and economic concentration of the popular music industry and the standardization of its products, the stylistic changes of jazz often terminate in mere manipulations for advertising purposes.

As far as there are any genuine developmental tendencies within jazz, they are bound up with this very tendency towards concentration and standardization, and with the desire to escape this tendency. The practices of the radio and recording industries have smoothed jazz more and more, have tamed its "shocking" features which never went very far anyway. Today, jazz practice tends towards two extremes. On the one hand, all its "corners" are being blunted, all its "rawness" is being sacrificed to a round, mellow, often over-sweetened sound. On the other hand, there is a trend to expand syncopation and rhythmical somersaults into a smart, virtuoso trick system that combines rhythmical sophistication and harmlessness. The advertising slogans "sweet" and "swing" refer to these two extremes. In practice, the difference is often much smaller than one would expect. Swing was first a countertendency against standardization and "smoothing" and originated with the best bands aiming at a bolder and more spontaneous style of performance. It was seized, however, at once by business.

Since Debussy the influence of jazz upon the art music of both continents has been considerable. It cannot be disputed that many "serious" composers tried to escape their isolation and get in touch with the public by experimenting with the highly successful and technically stimulating new kind of dance music. Even within autonomous production there is almost no composer who did not somehow react to the impulse of jazz. This is not only due to the so-called mood of the time and the supposed up-to-dateness of jazz but also to purely musical reasons. In serious music the emancipation from tonality and its intrinsic symmetries, and esp. the emancipation from the accent upon the down-beat, met the idea of jazz half-way. Mention may be made of Milhaud (*Le Boeuf sur le Toit*).

Hindemith (*Kammermusik* op. 24, No. 1; *Suite "1922"*), Krenek (*Jonny spielt auf*), and Kurt Weill (whose *Dreigroschenoper* was played from the beginning in jazz arrangement). The most important results of the process between art music and jazz, however, are probably Stravinsky's *Ragtime* and *Piano Rag Music*; and above all, his *Histoire du Soldat*. In the latter, the whole technique of jazz, particularly that of percussion, is put into the service of a genuine intention of composing which reveals, as it were, the hidden meaning of jazz itself. —T.W.A.

**jên wu** (Ch.). A style of painting which includes figures and objects of domestic environment.

**Jesuit style.** A style of church architecture developed by the Jesuit Order. It was the style of almost all of the churches of the 18th cent. Its main characteristic was an interior nave supported by two rows of superimposed columns, on either side a low aisle with flat ceiling, above which runs an open gallery; all features reminiscent of antique Roman architecture. —R.L.W.

**Jeu de Robin et Marion.** See MEDIEVAL MUSIC.

**Jeu parti.** See MEDIEVAL MUSIC.

**jewel point.** *Etch.* A very useful tool, the diamond or ruby point of which can be used with extraordinary freedom in making drypoints.

JEWELRY, HISTORY OF. In current precise use, the term "jewel" is applied to a gem that is worn on the person. But the term originally referred to an article of adornment, and this usage will be adopted here.

From the beginning, jewelry seems to have been closely associated with costume. Indeed, the sociologist, Edward Westermarck, believes that ornament preceded clothing, even that clothes have developed from decoration in some instances.

The parts of the body destined to carry ornaments were those contracted or narrower portions above large bony or muscular structures—the forehead and temples, the neck and shoulders, the waist and hips, the ankles, the wrist, and the fingers. This kind of decoration has often been carried out for reasons of pleasure. It is as if the figure has been considered a kind of vase or bowl. It has been conceived as a whole and in terms of the relations between subdivided parts. Parts may be accentuated by means of a necklace, a tiara, a brooch or a ring. As a potter would run a band of color around the rim of a bowl, the jeweler would border the extremities of the human body.

It must not be supposed, however, that jewelry has been designed for hedonic purposes alone. Throughout history articles of this class have enjoyed a wide range of utility, from the **talisman** which rendered its wearer invulnerable, to the clasp which secured his cloak. Devotional rings and beads testify to the part which jewelry may take in religious ritual. Jewelry has been employed for many other interesting reasons, for sexual attraction, for "conspicuous leisure", to imitate or emulate.

*Ancient Egypt.* A rich range of jewelry has been disinterred from the archeological sites of Egypt. The types of ornament include crowns, necklaces, pectorals, bracelets, anklets, and rings. Many techniques are represented—chiselling, molding, inlay, filigree, cloisonné. This period supplies the earliest instance of **granulated work** in which small grains of gold are soldered on a flat surface. Gold was commonly set with precious and semi-precious stones such as lapis-lazuli and turquoise, with pastes and even glass.

The selection of motifs was apparently determined by religious considerations. Many anthropomorphic and zoomorphic forms of the deities appear in the jewelry, as well as certain abstract figures of religious signification.

It is sometimes difficult to distinguish between the representations of crown and coiffure in the early periods of Egyptian art. Certainly it seems that the **vulture headdress**, the most important ornamental head covering of the early period, included a fabrication of more than hair. In later times, however, the distinction becomes clear, as may be seen in the tall crown of *Nofretete*, in the bust at the Berlin Museum.

Elaborate wigs were more common than caps or crowns. The early hairpins which secured the coiffure were bodkins, of single shaft, fashioned in bronze or gold.

Large silver or gold **hoops**, some more than two inches in diameter, were worn through the pierced lobe of the ear. In some cases, a pendant was suspended from the hoop. During the Ptolemaic period, under Greek influence, the hoop was shaped into a convex crescent which often took on a granulated surface.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Lapis-lazuli, carnelian, amethyst, felspar, agate and pearl in the form of drops, diamonds, cylinders, and flat disks were used singly as **amulets**, or in series as strands, amounting in some instances to ten concentric bands. Both men and women wore deep **collars** of string beads. Good representations are to be found on the male in the famous *Hunting Scene* in the British Museum, and on *Nofretete* at Berlin. Sacred emblems, such as the scarab, utchat, uraeus, and lotus, were worked into the pattern of many **necklaces.**

A plate of approximately four inches at the base was, on occasion, worn as a **pendant** to a necklace. Usually gold, this carried symmetrical designs of representational and symbolic figures which were engraved, enamelled, or inlaid with colored stones. Good examples are the *Pectorals of Sesostris II and III* at the Cairo Museum; and the *Pectoral from the Necklace of Princess Sathathor-iunut* at the Metropolitan Museum, New York.

Both metal and beads formed bands for the arm and ankle. Some were simple band rings, others were serpentine. Gold and silver were ornamented with enamel or with stone inlay. **Bracelets** were worn on both forearm and upper arm, as may be seen in the relief of *Seti Making Offering to Osiris* in the Temple of Seti I at Abydos. The Leyden Museum collection includes a *Gold Anklet* one-and-a-half inches high by three inches in diameter, bearing the name of Thotmes III.

While the less well-to-do classes wore **rings** of ivory and porcelain, the wealthy wore gold and rarely silver. Many metal rings were set with semi-precious stones. A red carnelian cut in the form of a scarab often formed the **signet ring** of the Pharaoh. Markings indicated the name of the owner, the ruling monarch, or were emblems of certain deities. Scarab, snake, snail, and knot patterns were popular. There are examples of settings which turned on pins. It was the fashion among women to wear many rings, two and three on a finger, and paintings on mummy cases testify that the thumb was not ignored. The use of the ring in the marriage service began in Egypt.

*Babylonia and Assyria.* The relief sculpture of this civilization indicates that both men and women wore necklaces, earrings, and bracelets. These were made of either gold or silver. In the Louvre Museum there are reliefs of *Gilgames, the Hero, A Winged Genie,* and *Worshippers* which illustrate the types of ornamentation employed by the people.

**Earrings** are usually long with pear-shaped drops or cones attached to a ring or a crescent. During later periods, crosses or groups of balls were favorite earring designs. Bracelets were worn on the upper arm as well as on the wrist, the upper arm bracelets usually being of the serpentine variety winding several times about the arm. Many of the bracelets clamped over the wrist and in some cases were ornamented with a rosette design. Necklaces were worn rather closely about the throat, some of them resembling "**chokers**". In the British Museum, a relief of *Ashurbanipal and His Queen at Dinner* depicts the royal family surrounded by attendants who are wearing closely fitting necklaces.

The British Museum and the University of Pennsylvania sponsored an expedition to the ancient city of Ur where many objects of ornamentation were found.

*Aegean Civilization.* Widespread excavation on the islands and along the shores of the Aegean Sea have revealed an extensive store of jewelry which was produced over a period of about 1900 years. The types of ornament include diadems, earrings, necklaces, bracelets, pendants, brooches and rings. Metal was worked in various ways, among them repoussé, twisted wire, and granulated work. The prevalence of motifs such as the sphinx, griffin, and bull's head point to a connection with religion.

**Diadems** reached an extreme of elaboration as in one example which, twenty-five inches in length, was covered with rosette ornaments in repoussé and further complicated by attachments of thirty-six large leaves of gold. **Fillets** with pendants of figures were worn on women's foreheads, the longest pendants falling on each side of the face. Certain other articles such as grasshoppers or tree crickets in gold repoussé suspended by chains likely were worn in the hair.

Gold butterflies, cuttlefish, rosettes and leaf designs were mounted on small **plaques** which in turn were perforated to allow attachment to clothing.

The Schliemann excavations at Hissarlik and the graves of Mycenae, the *Gold Treasure* at the Artemesion at Ephesus gave up a great variety of material including, as well as those already mentioned, cross and star motifs, meander patterns and concentric circles, spirals of twisted wire, and rosettes with fragments of stones in the center. Examples

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

of jewelry excavated on the Island of Cyprus between 1872-1875, which include enamelled ware, now comprise the Cesnola Collection of the Metropolitan Museum.

*Ancient Greece.* The many types of Greek jewelry include diadems, hairpins, earrings, necklaces, fibulae, brooches, bracelets and rings. While geometric motifs prevail, there are numerous representations of animal and human figures, some of which stood for the gods of the Pantheon. Greece inherited certain techniques from previous cultures, and it is common to find specimens of filigree, enamel, and granulated work.

Intricate designs in ivory or metal surmounted **hairpins** with a single shaft. In some instances, the designs were geometric; in others, they formed representations of figures or insects, such as the cicada. The most pretentious pins were ornamented with enamels and jewels, and were sometimes tipped with gold.

Plato, it will be remembered, mentions golden **earrings** in his will. Men as well as women are known to have worn this type of jewelry. Winckelmann reported that many of the statues originally had ear pendants. For the most part, rings were worn symmetrically, one at each ear. Later, however, it was the fashion to wear only one earring. Some earrings were very simple, but others reached a remarkable degree of complexity. One of the latter from the Golden Age shows in fine detail *Nike Driving a Two-Horse Chariot.*. This is owned by the Museum of Fine Arts in Boston.

Colored beads and stones were not generally worn. On the other hand, the goldsmith excelled in filigree work and in the arts of engraving and embossing. Many **necklaces** were made of plaited wire which terminated in pendants of enamel or chased gold. Others were formed by linking together various ornaments such as disks and balls. The characteristic Greek necklace, however, was a deep fringe made of fine chains and little vase-like drops. Rosette shapes in white, green and blue enamel were interspersed among the chains.

The use of **bracelets** seems to have been confined to women. Some statues show a simple bracelet encircling the upper arm. This is to be seen, for example, in the *Knidian Aphrodite* in the Vatican. Bracelets were made of gold, silver and bronze. Designs were either embossed or outlined by thin strands of gold wire in curvilinear arrangements. Gems were rarely used before the 3d cent. B.C. Cloisonné bracelets were fairly common.

The **finger ring** was introduced from Asia. Worn sparingly, in the early period it was restricted to the third finger of the left hand. Later on, it appeared on the index and little finger. During the Golden Age, rings were set with carnelian, jasper, and quartz with intaglio design. Others were set with sardonyx and chalcedony which lend themselves to cameo cutting.

*Etruscan Civilization.* While certain Etruscan designs bear a close resemblance to Greek motifs, others, in most cases later, are not so precise. Later pieces are relatively florid. Filigree and granulated work in gold attained such a degree of refinement that craftsmen of modern times were mystified and quite unable to imitate the process. In the last century, however, the method was restored to the common lore of jewelry by Castellani of Rome, who had discovered goldworkers in the Abruzzi to whom the technique had descended. Among popular Etruscan patterns were those known as the "**handbag**" and the "**gondola**" which were prevalent in types of jewelry with suspended parts such as necklaces and earrings. Gems were infrequently used, although pearls and even white glass have been found in a few examples. Cloisonné enamel is not unknown.

*Ancient Rome.* Rome carried on the Etruscan's love of gold ornaments for the person. As it was in the case of the other arts, Greek design was subsequently adapted to Italian taste. But where the Etruscans were spare in their use of gems, the Romans were lavish. Where the Etruscans decorated gold surfaces with complex patterns of filigree or granulation, the Romans preferred large plain surfaces. Greek design is fine and graceful; Roman design is magnificent and heavy.

**Hairpins** were made of gold, silver, or ivory and were seldom without some form of representational ornament. Dogs, bears, and military standards were frequently formed out of the superstructure of the pins, but more often the subjects had a quasi-religious significance and were drawn from the more amorous members of the Pantheon.

It has been said that the Greeks valued workmanship, whereas the Romans esteemed material. Certainly the costliness of an article seems to have inspired a respect which was mixed with other causes for admiration. For example, Seneca has said that some **earrings** were so expensive that their price was equal to the revenue of a large estate. A major

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

cause of such prodigious cost was the extravagant use of precious stones. Emeralds, rubies, sapphires, garnets and pearls were common embellishments of the ear.

If only by virtue of size, **necklaces** were among the most expensive items. There were ropes of pearls and it was no rarity to see diamonds, amethysts, sapphires and opals linked in generous lengths about the neck. Settings for these stones have been adapted by modern jewelers, and their like is now widely familiar.

The **serpent bracelet** seems to have been the most popular, but many others were more massive and ran even more to display. Some of these opened and closed on hinges. Broad bands or links provide elaborate settings for precious stones of several colors.

The prodigality to be found in necklaces and bracelets also is to be found in **finger rings.** Here, too, precious stones were conspicuous. Diamond, pearl or amber complemented the rich settings, and in some cases sapphires and rubies were cut as seals. Other rings were decorated with religious or mythological subject matter. There were iron as well as gold rings. At one time iron rings were worn as signs of mourning by knights and patricians who otherwise by right wore gold. Men and women of the Empire were laden with rings, even to the point of placing them above the second joint of the finger. Thumb rings were popular. Finger bands made convenient emblems of political, social and domestic functions. The **"key" ring** was a characteristic Roman institution. It is supposed to have derived from the seal which signified the right of the mistress to seal the household stores. Later, the stores were more firmly secured by a lock, the key being a projection from the natural body of the distaff ring.

*Byzantium.* When Emperor Constantine established his court at Constantinople, the fashion center of the world moved from the classical world to the Near East. Based on three stylistic sources, the Greek, the Roman and the Eastern, Byzantine jewelry, like its costume, was composite in its design. Earrings, necklaces, rings, tiaras and bracelets illustrate the luxurious taste of the day. The famous mosaic, *Empress Theodora and Her Court,* in San Vitale, Ravenna, pictures a lavish display of ornamentation upon the figures of her lady attendants. Both men and women wore jewelry.

Four different shapes were used for earrings—the circle, the square, the triangle and the crescent. Sometimes these were engraved someties pierced, at still other times were decorated with cloisonné. **Earrings** were often four inches in length. Pearls were one of the favorite gems—either used in a strand or combined with gold and other precious stones. **Necklaces,** in some instances, assumed such large proportions that they resembled wide collars. These were encrusted with jewels *en cabachon,* inlaid with colored pastes, or were simply heavy plates of gold. Filigree tracery and granulations are to be found on the collar necklaces as well as on the single strand necklaces and others of less ambitious design. Glass and clay were employed in lieu of the more costly materials.

*Middle Ages.* With the decay of the Roman Empire and the removal of the court to Constantinople, Europe saw the rise of the barbarian tribes. Now preserved in the Museum of Bucharest is the remarkable *Gold Treasure of Petrossa* which was discovered in 1837 in the Transylvanian Alps. This find indicates the type of ornamentation produced by the Goths. Its style is a decadent form of the classical tradition with barbaric elements included. Its chief characteristics are: conventionalized animal forms (i.e., bird-shaped **fibulae**); pierced gold work and a free use of stones inlaid in cloisonné fashion or in a perforated gold plate. The *Petrossa Treasure* contains objects which are similar to those found from Siberia to Spain. The migrations of the Teutonic tribes no doubt accounts for the dispersement of these objects. The later and more refined forms of this type of decoration are to be found in the Merovingian style of the 5th cent.

Of an equally long but independent line of descent is the Celtic jewelry. Typical of this style of decoration is the hammered work with details in repoussé and the fillings-in of vitreous paste, coloured enamels, amber, and in the later examples rock crystal with a smooth rounded surface cut *en cabochon.* The more ancient examples of Celtic ornamentation accent curves, skilful uses of inlaid enamels, and the chased line. After the introduction of Christianity, other motifs were introduced, such as interlaced winding scrolls which led to the complexity of Irish illumination and metal work. Examples of 1st cent. gold work is the find discovered in the northwestern part of Ireland. One of the finest examples of Celtic art is the *Tara Brooch* in the Royal Irish Academy, Dublin. This was found near Drogheda and is made of white bronze, copper, tin, and silver, the lower half of the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

ring being broadened out into a much-ornamented lunette. Scrollwork of fine wire, translucent enamels, filigree gold work, colored glass, little human masks in red glass ornamenting the large bosses make up the design of the brooch.

The contents of the tomb of King Childeric (5th cent.) in the Bibliothèque Nationale, Paris, are typical examples of the jeweler's craft of the Merovingian period. A thin slab of garnet was set on a plate of gold and secured by shallow walls of gold which were soldered to the surface. Sometimes very decorative details of filigree work, beading and twisted gold wire were added. **Buckles, girdle ornaments,** earrings, bracelets, rings and fibulae were other objects similarly treated,—hammered in relief, or set with precious gems.

Although based on the motifs employed during the classical era, the jewelry up to the 10th cent. is impressive because of its barbaric splendor. The refinement of the jewelers of Greece was no longer in evidence; its place was superseded by a heaviness and a richness, reflections of barbaric taste. The Gallo-Romans, the Frankish, and the daughters of Charlemagne wore this type. The Anglo-Saxons, on the other hand, used **beads** in great quantity. All sorts of material were used for these: clay, stone, crystal, garnet, amber and amethyst. This vogue for beads gradually declined with the result that during the Middle Ages beads became *passé* with ornaments of gold taking their place in fashion's favor. In the 14th cent. chains began to appear and were liked so much that it became the fad to wear several at once.

Invading barbaric tribes used **T-shaped fibulae** a great deal. The Celts and the Anglo-Saxons found **annular** and **penannular brooches** very much suited to their taste. During the later Middle Ages, a round brooch with the pin placed behind was developed out of the circle and long pin of the Celtic period. Until the 13th cent. the stones were polished but uncut.

The **bracelet** and the **earring** suffered because of the medieval type of costume. Although in the 9th and 10th cents., gold and bronze were popular, the long flowing sleeves of later date did much to overcome the fashion for arm decoration. The earring, too, shared the same neglect, for, although the Merovingian period continued the Byzantine taste for these articles of adornment, they gradually went out of style because of the medieval custom of using veils to swathe the head.

From the 10th to the 13th cents., the **ring** was the chief article of medieval jewelry. The massiveness of these rings was the result of the combination of the Byzantine tradition with that of the barbaric. There were many different types of rings: the spiral ring of gold, the betrothal ring, the wedding ring, the gift ring, ecclesiastical rings to indicate authority and the union of the priesthood and the church, and many others. During the 15th cent., **charm rings** were worn to invoke miracles, such as to bring about the ability to converse with the birds, and the power to become invisible. **Talismanic pieces** were set in rings for protection of one kind and another. For example, a wolf's tooth would be protection against assault; a badger's tooth would eventually bring wealth. One of the most popular rings was the **devotional ring** which was made of gold, bronze, or ivory and which had ball-like projections around it for the saying of "Aves".

*The Renaissance.* Even today jewelry has not outgrown the influences which were first imposed by the Renaissance. But while there is a family resemblance between objects of the craft which were made four centuries apart, the differences mark interesting divergences of taste.

The Quattrocento lady, for example, affected a profuse if dainty display of jewels which at times became indistinguishable from the surface decorations of her costume. It was not uncommon to fasten myriads of tiny pearls to a sleeve or a bodice. On the other hand, a close-set cluster of stones often served to accent some part of an ensemble. This occurs in many portraits of fashionable women, where a pendant of large pearls hangs isolated from a thin cord about the throat.

Women of Cinquecento, however, apparently scorned such preciosity. Their jewelry was rich and elaborate, but it was concentrated rather than diffuse and enriched by contrast with simple surroundings. A **brooch,** often the work of a master, would be the solitary decoration on a dress. A ring, a necklace, or a pin became, in the wearing as much as in the making, an epitome of the jeweler's art.

Later on, prodigality became once more the order of the day, and in turn a period of refinement set in. Yet throughout this flux, certain characteristics of the Renaissance prevailed.

The greatest artists of the time designed jewelry. Indeed, one of them, Benvenuto Cellini, was more celebrated for his creations in

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

this craft than he was for his sculpture. Leonardo and Dürer were among those who designed articles of personal adornment. Their predecessors included Mantegna, Verrocchio and Ghirlandaio.

Elaborate **chains** and **collars** composed of massive links were regarded as emblems of wealth and distinction when worn by gentlemen of the High Renaissance. A superb example of this practice may be seen in Titian's portrait of *Pietro Aretino,* the Frick Collection, New York. Women also wore chains about the neck, usually with jewelled settings and an expansive display of pearls. **Pendants** and **pendant brooches** were popular. *Isabel, Empress of Portugal,* is shown by Titian in the picture at the Prado wearing a large brooch which divides a heavy rope of matched pearls into two deep loops. Antique **cameos** also were esteemed by the quasi-scholarly society of the period. In the 17th cent., brooches were pinned like a badge to hats for men, whereas both men and women used them to keep lace collars in place. At the close of the century the brooch became unfashionable.

Toward the middle of the reign of Louis XIV, stones took precedence in importance over settings. A lapidary known as Jaquin of Paris invented a process for making **imitation pearls.** Blown glass beads were lined with powdered fish scales and filled with wax. During the Revolutionary period in France luxurious ornamentation was viewed with suspicion. A simple ribbon was substituted for the necklace; only later was the miniature or the locket added as a pendant to this.

**Earrings** added to the spectacle of Renaissance dress. For a time, they were an item *de rigueur* in the gentleman's costume. Charles I, Raleigh and Essex were exemplars of the mode. The pearl was the favorite gem for the ear until early in the 18th cent., when the brilliant-cut diamond replaced it. Bracelets were seldom seen until late in the 18th cent., shortened sleeves having become the vogue.

**Rings** were lavished on fingers and thumbs in the 16th cent.; and if there were still too many, the excess numbers were carried on a chain from the neck. Portraits of Holbein of *Jane Seymour, Anne of Cleves,* and others testify to the admiration of rings in those days. Among the several novel types of ring was the "**posy**", with inscriptions such as "Let us love like turtle-doves".

Portraits by van Dyck and Sir Peter Lely illustrate the sudden lapse of popularity of the ring. Indeed, later on, even the custom of the wedding ring was given up, on the basis of its un-Christian origin. The execution of Charles I revived an earlier habit of wearing "**memorial rings**". The **mourning ring** was in fashion for a while. It was usually black, massive in design, and often bore a portrait of the deceased with an appropriate inscription. Certain rings of this order contained a twist of the deceased's hair.

*The Nineteenth Century.* The Industrial Revolution converted the art of jewelry from a hand-made production and individual creation into a commercial industry and large-scale mass production. Instead of a bracelet being created as an independent work of art, it now very frequently became merely one of a set. During the 1840's, black onyx and jet with gold and pearls were used for sets of brooches, bracelets and earrings. At about this same time, necklaces were seldom seen. For a decade or two following, jewelry seems to have declined in public favor, but gradually it came back into style again. Coral and enamel brooches were a lady's delight to be worn with her Cashmere or Paisley shawl, lace collars, or fichus. Gold, silver, and glass as well as precious stones were likewise used for brooches. **Rings** were very popular in the early 19th cent. One of the most interesting styles in the history of the ring occurred during the Napoleonic era. After Napoleon's exile, his still faithful followers wore rings which had a stone set in a hinged lid. This lid opened and inside there was concealed the portrait of Napoleon. The ring, like other articles of jewelry, was not worn very much until 1865 when the signet ring became very popular. This fad was followed by a flair for cameo rings which produced a taste for intaglio rings, cut in black onyx, carnelian or "sard". In the 1870's long gold and enamel **earrings** with gold fringe enjoyed short-lived favor, for in the decade between 1880 and 1890 the popularity of the earring declined. But in 1900 the screw device was invented with the result that the earring came back into style again. While the earring was not being employed as an object of decoration in the 1880's, the **bracelet** was developed into a serpent design which twisted about the arm heavy circlets of gold ending in some favored animal's head. The late 19th cent. saw the manufacture of long bars of pressed gold used for brooches, the cost was modest because of machine production. **Lavalieres,** named after the famous

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

French beauty, Louise de la Valliere, were *haute mode.*

About 1880, a reaction to machine-made jewelry set in. A jeweler whose name was Massin created designs very unlike the necessarily more rigid patterns of a machine product. He used motifs inspired by natural flower forms and emphasized the craftsmanship of his design. Another artist René Lalique turned away from commercialism and relied upon the designs of past traditions. He used free double curves, opalescent harmonies of colouring and was influenced by the ancient jewelry of the Orient, Egypt, Chaldea, Greece and Italy. He ignored the hierarchy of gems, using a piece of flint if his design warranted it. He believed that no stone had any value beyond the characteristic expression he lent it as a means to his end.

The "arts and crafts" movement in England purged the jeweler's craft of its character of mere gem-mounting. Feeling the need for the creative hand of the artist to come into direct contact with his craft, many people, among them L. C. Tiffany of America, and Philippe Wolfers of Belgium, allied themselves to this movement because of the disastrous effect the machine had had on the art of the jeweler.

*The Twentieth Century.* Jewelry has become in this century a large modern industry with centers at Paris, Vienna, London and New York. Jewelry seems to fall into three classifications: that in which gems and stones form the principal portions with the metal merely used as the support; that in which the gold or silver or platinum work is an important element in the design with the gems subordinated to the metal; and that in which the gold or other metal is used alone. The designs are wrought out by hammering in repoussé, casting, engraving, chasing or by the addition of filigree.

**Bracelets** during this time have been in and out of fashion, depending upon the sleeve length. Wrist watches have developed into a kind of bracelet. Gold, silver, platinum, precious and semi-precious stones are used for bracelet design. Sometimes even compositions of one sort or another are called into use since the advent of so-called **"costume" jewelry.** Because of the fleeting fashions in dress and the rapidity with which change follows change in this century, the industry of "costume" jewelry, made of imitation stones and metals, and so forth, has been created. Necklaces, clips, pins, rings are products of this industry as well as products of the more expensive jewelers.

The 20th cent. has made three contributions to the field of ornamentation: "costume" jewelry; the introduction of platinum jewelry; and the revival of hand-wrought jewelry. Working at present in the tradition of the Renaissance craftsmen are many artists, among them some who have made their name in other fields of art. Salvador Dali, the painter, has used precious stones and metalwork in a fantastic way. Like Lalique, Alexander Calder, known chiefly for his mobile sculpture, shows less respect for precious material than for design. His most notable pieces are composed of twisted copper wire and hammered brass. See Alexander, Christine, *Jewelry, the Art of the Goldsmith in Classical Times,* 1928; Allen, J. **JEWISH ART.** This term can hardly be found before the 19th cent. when discussions were conducted concerning the essential Jewish contributions to civilization. Even those who think of Judaism as a nation, which has temporarily lost its political organization but never its national qualities, do not claim the existence of a Jewish art. The term, however frequently used, refers to art for Jews and Jewish religious purposes, or to artistic creations by Jews. There is no specific tendency toward form or content in the artistic creations of Jews or for Jews, but there is an intimate connection between their works and the art forms and tendencies of the peoples among which Jews have been living. There is no connection in the art works of Jews binding them through space and age to a Jewish art, nor to a complex group of distinct artistic patterns, nor is there evidence for a need toward artistic expression as a result of an artist's Jewish origin.

The reasons for the non-existence of a Jewish art are among others: the interpretation of the second commandment, leading to great reluctancy in accepting the possibili-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

ties of the fine arts. That attitude changes from rejection of the arts to indifference toward art, but never to an acceptance of the fine arts as a function of life. Though the Bible sees the artists like the prophets filled with the spirit of God (*Ex.* 31, 1ff., 35, 30-36, 1ff.), the rabbis and sages are not inclined to have the arts enter into the religious life of the Jews. A further reason for the non-existence of a Jewish art (in the sense of Italian art, French art) are the political-social conditions under which Jews have been living. Lack of security and forced migrations, as well as exclusion from guilds and crafts made the development of technical knowledge and craftmanship impossible.

Because of these limitations the history of art of the Jews centers primarily in architectural tasks. After the canaanitic time with its Egyptian influences, tendencies of the Near East joined with those Egyptian trends in the Temple of Solomon (by 1000 B.C.). Political conquest by Babylonia and Assyria caused a strengthening of the West-Asiatic influence. The Temple of Herodes (1st cent.) was built in Hellenistic forms. The synagogues, developed first in Egypt around 250 B.C., are basilicas, often with two stories (q.v. synagogues). Jewish catacombs are found in Malta, Syracuse, Rome and North Africa.

In the minor arts influences can similarly be drafted. The art of glyptics shows the Phoenician sources, ceramic excavations represent Amorite and Phoenician influences. There are no remains of metalwork, but the Jews in Palestine seem to have known the technique of covering wooden carved forms with silver or gold plates (Golden Calf, doors of the Temple). Ivory-carving was used for the throne of Solomon. There is no example of sculpture in stone or clay. (For wall painting see Dura-Europos.)

In medieval and modern times the religious cult stimulated works in silver, gold, textiles and ceramics for domestic and synagogal use. The decorations for the Scroll, textiles for the Holy Shrine, lamps and spice boxes were decorated with Jewish symbols, among them the chandelier with seven arms, the signs of the Zodiac and others. Many of these works are certain to have been created by Jewish craftsmen and artists. Bookwriting and printing became a main chapter of Jewish artistic interest. The earliest manuscripts with Hebrew texts are Pentateuchs of the 10th cent., mostly from Egypt and Syria. The earliest known European examples were written in Spain around 1200. Many manuscripts were *Haggadahs* (q.v.), written in Italy, some in France and Germany. Other manuscripts with illustrations were the "Story of Esther" and prayer-books. The Italian Jews in the 17th and 18th cents. had richly illuminated marriage contracts. Though the artistic styles from Gothic to rococo are to be found in the miniatures, there is a tendency to perpetuate traditional forms and subject matters in the way of a folk art. See JEWISH MUSIC; also *Encyclopedia Judaica; Jewish Encyclopedia;* E. Cohn-Wiener, *Die Juedische Kunst,* 1929; K. Schwarz, *Die Juden in der Kunst,* 1936; *Schriften der Gesellschaft zur Erforschung Juedischer Kunstdenkmaeler.* H.Gu.

**Jewish hora, the.** See hora.

**JEWISH MUSIC.** *Music in the Bible.* That music played an important part in the life of the Jewish people from the earliest days of its history is attested by the many musical references to instrumental music and song found in the Bible. The Song of the Sea (*Exodus* 15:1-20), which was sung to the accompaniment of a percussion instrument, as well as the account in the latter part of the Bible (*Chronicles* 2, Chap. 29:26-30) of the part which song and instrumental playing played in the observation of a Passover during the reign of King Hezekiah, point clearly to the place of music during Biblical times.

Everywhere and at all times was music to be found among the Jews in Biblical days. Children danced in the streets and young people played various percussion instruments and the Kinnor (small harp). Music at meals was quite common, but the use of dancing girls for entertainment was censured by the Prophets. Dancing, however, was common on religious occasions and celebrations. David danced before the Lord, and so did Jephtha. Much dancing took place at the celebration of the Ceremony of the Water Libation on the second night of the Feast of Tabernacles. The music which accompanied these dances was chiefly rhythmic. Melody played a secondary part. The instruments were played in unison and without harmony. Music was heard in private life at weddings and funerals as well as in public life, when a warrior returned victorious or when a king was crowned. We find (Samuel I, 18-6) that David danced before the Ark of the Covenant when he recaptured it from the Philistines. The music in the First and

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Second Temples was performed by a choir of Levites and instrumental players. The following account of a temple service in the last century B.C.E. is given in the Mishna (Tammid V) : After the priests on duty had recited a benediction, the Ten Commandments, the Shema (*Deut.* 6:4-9), the priestly benediction (*Num.* 6:22-26) and three other benedictions, they proceeded to the act of the offerings. After they were through with the arrangement of the sacrifices, one of them sounded the Magrepha which was the signal to enter the Temple in order to prostrate themselves, whereas for the Levites, that sound marked the beginning of their musical performance. Two priests took their stand at the altar immediately and started to blow the trumpets. After this performance they approached Ben Azra the cymbal player, and took their stand beside him, to the left and right. At the sign of a flag given by the superintendent, this Levite sounded his cymbal, and the Levites began to sing the Psalm of the Day. Whenever a section was finished they paused, the priests repeated their blowing of the trumpets and the people prostrated themselves.

The texts sung by the Levites were not only the Psalms, but also sections of the Pentateuch.

*Music in the Psalms.* Song occupied the more important part in religious worship, as compared to instrumental playing. In Psalm 137, the Israelites in Babylonian captivity are asked to sing the "Songs of Zion", for these songs had become well-known for their beauty. Many are the references in the Book of Psalms to the musical instruments and to the popular songs of the day. Psalm 150 gives us a good idea of the wind, percussion and string instruments used in Biblical days. The Book of Psalms has become the chief pillar of Christian Liturgy. Such terms as "Amen", "Hallelujah", "Hosannah" (Hoshia-na) have been taken over from the original Hebrew. St. Paul and Pliny the Younger acknowledged that Christian songs and hymns were taken from the Jews.

*Cantillation.* Poetry, lore and prayers were studied to song, for through song the word was more easily remembered and the meaning of the word became clearer. All study and reading of the Torah among Jews was commanded to be done "in sweet musical tones" for it is written that "whosoever intones Holy Scripture in the manner of secular song abuses the Torah" (B. Meg. 32A. San. 101A).

The music with which the Torah is intoned is called cantillation. These cantillation melodies, known as *Ta-amim* or *Neginoth,* existed long before their syntactical force was felt and were in the general musical style of the songs which the people sang in those days. The signs are to be found above and below the Hebrew word in the Bible and serve to remind the reader of a group of notes which each sign denotes. These signs are either conjunctive or disjunctive. Some are prepositive, others are post-positive. Most of the signs are to be found on the accented syllable of the word. In some cases, where there are two or more syllables, two or more signs may be found.

Only those books of the Bible which were read in public are provided with cantillation modes. They are Pentateuch, Prophets, Esther, Lamentations, Ruth, Ecclesiastes, Song of Songs, and in some communities, Job. Proverbs, Ezra, Nehemiah and Chronicles have no modes because they were not read in public. Eighteen accents are used for the twenty-one Books, and twelve for the Psalms, Proverbs and Job. Three systems of signs have come down traditionally, viz.: the Palestinian, Babylonian and Arabian. The Palestinian system of cantillation has been adopted by Western Jewry.

The cantillation modes and interpretation of the many tropes vary according to the need of the text and occasion. The tropes are interpreted differently for the reading of the Pentateuch and for the reading of the Prophets. A special interpretation of the tropes for the Pentateuch is employed on the New Year Day and Day of Atonement. Special modes are sometimes used for certain parts of the Bible, as for example "The Song of the Sea". These Biblical intonations were preserved in the memory of the people for many centuries.

Attempts were made, however, to preserve neum interpretations by such ancient nations as the Indians and the Greeks. These attempts constitute the first efforts at musical notation. This system of "ear-marks" consisted of lines and curves which the voice was to make.

A system of chironomy practiced in ancient Palestine and up to the 12th cent. in Bagdad and even to this day in Yemen, consisted of manual accents, whereby the rise and fall of the finger by an assistant shown to the reader, served to remind him of the trope associated with the word.

There were teachers at all times who taught musical accentuation and the art

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

of chironomy. Private scrolls with musical accents came into existence gradually, but the first to furnish the Bible with a complete system of accents was Aaron Ben-Asher of Tiberias in the 10th cent. The Ben-Asher family, from the 7th cent., seemed to have been interested in musical accentuation. In public, however, the reading had to be done from an unpointed and unaccented parchment scroll.

Upon examination of the various ancient systems of cantillation one is led to believe that the pentatonic scale must have been the scale which was prevalent and which was used by the people in their daily music.

Tropes frequently serve to accentuate the meaning of the word and to define its fine shades of meaning. They frequently are aids to grammatical analysis. When intoned by a capable reader, the cantillation of the Bible gives us a fair idea of the spirit and manner of ancient recitation. These cantillation modes served as the foundations of the early church chants which later crystallized into the Gregorian chant of the 5th cent.

*Prayer Modes.* The cantillation modes influenced the formation of the prayer modes. Israel not only praised and adored his God, but he also cultivated supplication. The Psalter is not only a book of praise and song, but a good part of it is comprised of prayer and supplication.

As time went on new prayers were improvised by the precentors who led the religious services. Many of these prayers found their way into the prayer book which was finally written down in the 5th century. Around these prayers and laudations for every day, holiday and ceremony in the Jewish calendar year, a tremendous musical structure was built, during Biblical days and through 2000 years of exile. Distinctive traditional modes and melodies were evolved for every holiday, and for every service celebrating a holiday. Special melodies were evolved for such special prayers as "Kol Nidre", for the evening service of the Day of Atonement and for every similarly important prayer. The prayer modes are based on certain scales. Out of these scales motifs are extracted and upon these motifs the cantor or precentor improvises his prayer. Sometimes at a certain point the cantor may modulate to another mode, but he will almost always manage to return. While these modes and melodies seemingly stem from the pentatonic scale, we can best understand them when related to our scales of today.

1. Magen Avoth Mode: d-e-f-g-a-b$^{b}$-c-d.
2. Adonay Malach Mode: c-d-e-f-g-a-b$^{b}$-c.
3. Ahavah Rabbah Mode: e-f-g#-a-b-c-d$^{(\#)}$-e.
4. Slicha Mode: d-e-f-g-(a).
5. Viddvi Mode: c-d-e-f-g.

*Unrhythmical and Rhythmical Chant.* We still have a great deal of unrhythmical chant in Jewish liturgy but rhythmical poetry influenced Jewish liturgy through the development of Islamic poetry in the 6th cent. Beginning with this period a large number of paytan-chazannim (poet-cantors) arose. For the rhythm which came to this new religious poetry, specialized handling was necessary by those musically gifted. This gave rise to the professional chazan or cantor. It was common practice in those days (and even in our own) for any worshipper who knew the prayers and modes, to lead the religious service. In many cases in mediaeval times and in some cases today the offices of rabbi and cantor are combined. Among these paytan-chazannim were Jose ben Jose (ca. 500 C.E.), Yanai (ca. 100 C.E.), composer of Mahzor Yanai, and Eliezer Kalir (ca. 700 C.E.). These lived not only in Europe but also in Palestine.

Many of the traditional melodies known to the western synagogue are believed to have been composed between the 13th and the 15th cents. A number of these are attributed to Rabbi Maier of Rothenberg (Worms, 1215-1293). Some of these melodies may here and there show western influence, but one can always find in them the traces of the cantillation modes.

*The Cantor.* Persecution, which is usually followed by ignorance, eliminated the honorary precentors and made way for the professional cantor. The rise of the troubadours in France and the Minnesingers in Germany in the 16th cent. made the Jews, too, feel the need of one who would express for them their prayers and sentiments in a musical manner. Soon the cantor became a very important factor in the Jewish community. He officiated at all services, while the Rabbi preached only from time to time during the year. The cantor in the community expressed the joys and sorrows of the people and was with the members of his congregation from birth to death. This circumstance led in some cases to conceit among cantors and neglect of study and duties. They were frequently censured by the Rabbis for attempting to bring in foreign melodies into the synagogue. But the people always followed the cantor, for

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

he was their only means of musical nourishment.

Young men with beautiful voices turned to this profession. Concert and operatic careers were out of the question for religious reasons. We have records of cantors who possessed great voices during the 18th and 19th centuries. In some cases cantors possessed creative talents and contributed compositions to the musical liturgy of the synagogue. Israel Lowy (1773-1832), Solomon Kashtan (1781-1829), Solomon Sulzer (1804-1890), friend of Schubert, Solomon Naumbourg (1815-1880), Hersch Weintraub (1811-1882), Osias Abrass (1880-1896), Abraham Baer (1834-1894), Pinchos Minkowsky (1859-1924), were some of the great cantors of the 19th cent. who helped to develop the music of the synagogue.

In our own time we have had a number of cantors with great voices. Among the most important are Josef Rosenblatt, Zavel Kwartin, Mordecai Herschman, Don Fuchs, David Roitman and Adolf Katchko.

There were also cantors with lesser voices but with strong creative ability, such as Yeruchum Hakaton (1798-1891), Nissi Belzer (1824-1906), Abraham Frachtenberg (1861-1929) and Baruch Schorr (1823-1904).

*Zemiroth.* The Sabbath has always been considered a day of "delight" among Jews. The singing of the 92nd Psalm, abounding in musical terminology, represents one of the many ceremonies which took place on that day in biblical times. Mourning on the Sabbath was prohibited even during the gloomy period of exile, and the singing of the Zemiroth—appropriate table songs at the Sabbath meal—was particularly encouraged. At a later date, the Cabalists propounded the belief that an additional "Sabbath Soul" may be induced to descend upon the Jew through the medium of song. The character of the community often influenced the types of melodies to be used for its "Zemiroth", most of which were composed since the 10th cent. onward. The Chassidim used highly rhythmic and joyous tunes, generally, while the Chabad Chassidim used prayerful and mystical ones. (*The Sabbath In Music.* A. W. Binder.)

*Folk Song.* There is no question as to the existence of secular songs during Biblical times. For a people in its own land and on its own soil creates, along with other values in civilization, its own folk lore. Ben Sirach (Chap. 30-40) praises song at a wine banquet, while he warns the people against association with female singers. Sages maintained that songs of wine and lust cause destruction in the world, while Israel's sacred songs save it (Shir Hashirim, Rabah, 8-end). It was generally maintained that when one had a good voice, he was to honor God with it. If we are to accept the Psalm headings, like Al Yonath Elem Rechokim (Psalm 56), and Ayeleth Hashachar (Psalm 22) as referring to popular songs of the day, and that these Psalms are to be sung to their tunes, this should give us additional proof that folksong singing existed during Biblical days. It is also maintained that the Song of Songs was a series of secular folksongs, incorporated into the Bible when a sacred interpretation was given to them. This interpretation spoke of God as the lover and Israel as the beloved.

After the Destruction, the Jewish ear was forbidden to listen to instrumental music. The use of secular song was forbidden (Hoseah 9-1). But the love for Israel's land was constantly in his heart. This he expressed through prayer and song in the synagogue. He hoped and prayed for return to his land where he might again be a free nation among other nations. This sentiment expressed itself in various forms of poetry which was set to music. So the earliest folksongs of Israel dealt with Israel's longing and hope for return to his land led by the Prophet Elijah, who was considered the legendary guardian of Israel's land (Mal. 3:23-24).

We have no folksongs recorded until the 18th cent. Even when they did come into existence their texture was of a religious and ethical nature. They were songs dealing with the various holidays. In these songs customs and rules for the observation of holidays and festivals are given. The oldest of these published collections is Simchath Hanefash (E. Kirchan; Furth, 1727).

The ghetto walls which rose in the 16th cent. gave rise to the Jewish secular song. The first German text collection of folksongs was compiled by Eisik Walich (Worms 1595-1605). Many of these songs were a Judeazation of German folksongs. One also feels here the influence of the troubadours and minnesingers of the 16th cent.

The ghettos of eastern Europe huddled the Jews closely together in small areas where signs of nature were scarce, and so we find in the songs of the 18th and 19th cent. very few which deal with nature and the outdoors. They do, however, traverse the entire gamut of human emotions from the cradle to the grave. (Jüdische Folks Lieder—Kipnis.)

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

The texts of these songs are sometimes original and sometimes translations, with some variations, of the songs of the people among whom the Jews lived. When the subject is a religious one, as, for example, God, the Torah or Israel, we may be sure to find an original text.

The same may be true of the music, whereas with secular subjects we almost always find borrowed tunes. The contrary is true when a religious subject is used. And so the most original Yiddish folksongs are those where the text and the tune are of Jewish content. (*Die Schönsten Lieder der Ost Juden*: Kaufman: Leipzig, 1920.)

*Music of the Chassidim.* The Chassidic Sect, which was founded by Israel Bal-Shem Tov at the beginning of the 18th cent. (*Romance of Chassidism,* Minkin), contributed greatly towards Jewish folk-lore and song. Music became an integral part of the Chassidic program. The slogan of this new sect was "Serve the Lord with Joy", and music became the hand-maiden of this slogan.

The Chassidim developed two types of songs. The first was a meditative type which was utilized when the Chassid attempted to throw off his earthly garb and rise to heavenly heights, there to join his soul with that of his creator. The second was the dance type which was used for moods of high exaltation. Both were frequently sung without words at Chassidic gatherings. Many of these tunes (Nigunim) were joined to prayer texts when sung in the synagogue. Emphasis was, however, placed on the Nigun, the song without words. The Chassidic Rabbi, Shneor Zalman, of Ladi (1747-1813) believed that in a song without words the heart can express itself to the full, whereas in a song with words the song must cease when the words come to an end. Rabbi Nachman of Bratslaw (1772-1811), another great Chassidic Rabbi, told his Chassidim that "There are gates in Heaven which cannot be opened save through the power of song". Some of the Chassidic Rabbis were musically gifted and composed tunes which their Chassidim sang and which became associated with a particular Rabbi. Rabbi Levi Yitzchok of Berdichev (1740-1810) is the poet and composer of a number of folksongs which may be considered as genuine examples of the Yiddish folksong. Among them are "A Din Toireh Mit Gott", "Dudele", "Mayerke Mein Zuhn", "A Gesang Funm Berditchever Rebben".

Those who opposed this new Chassidic sect were called "Mithnagdim". They sang pseudo-Chassidic songs, in which they ridiculed the Chassidic Rabbi, his followers and the relationship of both. These must not be confused with the songs which the Chassidim themselves sang. Examples of Mithnagdic songs are: "Der Rebbe Hot Gevolt", "Der Filizof", and "Nissim V'nifloos". (*Chassidic* Songs: A. W. Binder.)

*Palestinian Folk Song.* The love for Palestine and the hope of returning to his homeland never died in the heart of the Jew, from the day when he was exiled and throughout the two thousand years of exile. This hope expresses itself in various forms of literature, poetry, prayer and music. It reached its climax during the Middle Ages with the Golden Age of poetry in Spain from the 10th to the 15th cents. This period brought forth the greatest of Jewish poets, Jehudah Halevy (ca. 1085-1145), in whose poetry Palestine was glorified. His longing to see the land (which, indeed, he did) is expressed in numerous poems (*Selected Poems,* Jehudah Halevy. Translated into English by Nina Solomon). This hope persisted and manifested itself through religious and secular poetry and reached its climax when an actual effort to resettle the land in 1881 was made by the Bilu settlers. Eliakum Zunser was one of the first to write of this return. His songs, "Shivas Tsion", "Die Soche" and "Die Blum" (*Songs of Eliakum Zunser,* New York), became very popular among the early Zionists. During this time, too, Naphtali Herz Imber (1856-1911) wrote his poem *Hatikvah* (The Hope), which became the Zionist Anthem in 1897. From that time on many folksongs of Palestine came into being. Many Yiddish folksongs were translated into Hebrew and many original poems were composed and set to music.

In most cases the music applied to these songs in the diaspora, as well as in Palestine, were borrowed from the countries in which the composer formerly lived. But there was the desire to create a Palestinian folksong, a desire not to be fulfilled until fifty years later.

The Balfour Declaration, issued in 1918, after the World War I, started emigration to Palestine, particularly from eastern Europe. During this period a great many folksongs were composed and sung, about every phase of Palestinian life. The people of Palestine, however, regretted the fact that these songs were not Palestinian in character, but borrowed for the most part. (*New Palestinian Songs*—Book I, A. W. Binder.)

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

In the early 30's of this century Palestine began to develop a new type of folksong and was singing more discriminately. Melodies began to be classified as "exile melodies" and "eastern melodies". The new favorite tunes were characterized as having a distinctive "eastern" flavor. Palestine at that time was singing a new song, composed not by the professional composer, but by the peasant folk. Upon analyzing the tunes of Zaira or Matithyahu Weiner, the most popular of Palestinian song-writers, and some of the new tunes created by others, we find that these new songs draw from three musical sources: (1) The Jewish liturgical song, (2) Yemenite songs, (3) The song of the Palestinian Arab.

The new Palestinian songs have musical figures which interpret Jewish folk-ways and Jewish characteristics. In these we find also expressed the longing of the Jew for his homeland, as well as the enthusiasm which he experiences in working toward its rehabilitation. (*New Palestinian Songs,* Book II, *Palestine in Song,* Book III, A. W. Binder.)

The most distinguishing features of the songs of this period are not as yet found in the melodies, but in the rhythms, tonalities and texts. Almost all contain rhythmic features which are buoyant, moving, enthusiastic and in some cases individual. These are indeed different as compared with the folksongs of the exile, which in most cases are sad, slow-moving, monotonous and imitative.

The songs of the latter part of the 30's represent a constant striving towards a purer style. Many of the songs show pentatonic characteristics, liturgical and cantillation elements.

*Harmonization.* The problem of the harmonization of the ancient and modern Jewish music has occupied the minds of all serious Jewish composers of the present decade. The western harmonic system of the 19th cent., when applied to the harmonization of Palestinian folksongs, does not reflect the spirit of this highly characteristic oriental music. And so composers, during the last decade, have been experimenting in many ways with new harmonic styles in the effort to bring out the true color of the Palestinian song.

Folksongs of Palestine reflect the many-sided musical experience in Palestine, as well as the activities of its inhabitants. There are national songs, watchman's songs, shepherd songs, hora (dance songs), love songs, songs praising various localities in Palestine, and worker's songs. The most characteristic and purest of these come from the Chalutzim in the rural localities. Among the best-known composers of modern Palestinian songs are M. Zaira, M. Weiner, Y. Ezrachi, N. Nardi, S. Fastalsky, N. Gurachow. (*Pioneer Songs of Palestine,* Book IV, A. W. Binder.)

*Synagogue Music of the 19th and 20th Centuries.* The impact of the tremendous development of Catholic and Protestant church music during the 17th and 18th cent. did not fail to make itself felt on the music of the synagogue. The musical performing structure of the synagogue at the beginning of the 19th cent. was composed of the cantor, a boy singer and an adult. This adult was a bass when the cantor was a tenor and vice versa. This combination sang in unison most of the time, hummed a chord during certain portions of the cantor's improvisations and improvised harmonizations during the rehearsals and at the service. Frequently the harmonization at the rehearsal was different from that which was heard at the service. This was done without musical notation, for musical education as such was prohibited, even as were the other sciences and arts among the Jews. Religious education alone was permissible. But musical reformers appeared during the latter part of the 18th cent. in the person of Israel Lowy (1783-1832), who began to bring ordered and rehearsed choir singing into the synagogue from musical notation. It was, however, left to Solomon Sulzer (1804-1890) to bring order into the music of the synagogue, when he assumed his position as cantor of the Kultus-Gemeinde Synagogue in Vienna in 1825. His influence was felt throughout all European synagogues, reform as well as orthodox. His compositions for the synagogue, which are embodied in his two volumes entitled *Shir Zion* gradually became the musical liturgy of the synagogue. His influence is felt even to this day.

Louis Lewandowski (1821-1894) in Berlin followed in the footsteps of Sulzer, as did also Solomon Naumbourg (1815-1880) in Paris, as well as a host of other composers of synagogue music who were both cantors and choir directors.

While these musical reforms did much toward bringing harmony out of chaos in synagogue music, they deserted for the most part, the musical traditions of the synagogue. This was in keeping with the spirit of the reform movement which swept over western Europe along with the period of emanci-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

pation in the first part of the 19th cent. These reformers wanted their music to sound Protestant-like, and the composers of synagogue music accomodated them. They endeavored to eliminate all oriental traces found in synagogue music. They eliminated the cantillation modes of the Pentateuch when it was read on the Sabbath, and the traditional melodies and modes of the synagogue liturgy, substituting for them the musical style of the Protestant church of that time.

While eastern European composers liked the newly ordered music, they felt that the music of Sulzer and Lewandowski was alien to the synagogue. So men like David Nowakowski of Odessa (1848-1931), Baruch Schorr of Lemberg, and Nissi Belzer of Belz, Russia, took these new forms and employed them while utilizing for the most part traditional musical material. This improvement came toward the end of the 19th cent.

The western harmonic structure was not always successful in serving as a harmonic background for these ancient oriental modes and melodies. Efforts, conscious and unconscious, were made now and then to reconcile melody and harmony. Some successful results were achieved in the works of Hirsch Weintraub (1811-1882) and Eleazer Gerowich (1844-1913). But it was David Nowakowski in Odessa who succeeded to the greatest extent toward this end. His two splendid published works "Neilah" and "Shire David" and many unpublished manuscripts are proofs of this fact.

*Synagogue Music in America.* In our own country the composers of synagogue music who came here during the middle of the 19th century were of meagre stature. The best which they achieved resulted only in a mediocre imitation of Sulzer and Lewandowski. Especially in the reform synagogue, where there was a new liturgy and no music to accompany it they were faced with a difficult situation. The first American composer of synagogue music for the reform synagogue to achieve some distinction was Edward Stark (1863-1918), cantor of Temple Emanuel of San Francisco. He was the first composer in this country to make an effort to preserve the musical tradition for the reform synagogue in America.

Gradually the synagogues began to feel the lack of Jewishness in their music. The third edition of the Union Hymnal (edited by A. W. Binder, 1931) makes use of many traditional melodies and modes. The reform synagogue gradually attracted musicians who were interested in preserving the Jewish musical tradition and so in the twenties and thirties of this century a large number of musical liturgies by such composers as Joseph Achron, Ernest Bloch, Frederick Jacobi, Isidore Freed, Lazare Saminsky, Jacob Weinberg and A. W. Binder and many others were published. These services combined tradition, musical technique and a striving towards a harmonic system in consonance with the musical material.

*Jewish Art Music.* The consciousness of the existence of a Jewish folksong and the development of the folksong in Palestine led many composers in Europe and America to apply themselves toward the arrangement and development of this material. Through the Jewish Folksong Society, organized in Petrograd in 1908, many folksongs were collected and arranged for concert performance. Many compositions in all forms were composed in which were utilized the various types of Jewish musical material collected. These compositions range from simple folksongs to chamber and symphonic works. Active in this group at that time were Julius Engel, Joseph Achron, Solomon Rosowsky, Moses Milner, Alexander Krein and others. A number of these pioneers in Jewish art music came to America after World War I. They brought with them their music and their ideas, which immediately influenced many of the younger Jewish composers in this country. The Zimroh Ensemble, headed by Simeon Bellison, clarinetist, was instrumental in performing much of the chamber music which was produced by the Jewish Folk Song Society. In 1931 Maillam, an organization for the support of music in Palestine, and for the performance of Jewish music in America, was organized by Solomon Rosowsky and later headed by Mirian Zunser. This organization functioned for eight years.

The Jewish Music Forum, was established in September 1940, with the purpose of enabling those interested in the history and development of Jewish music to gather and discuss their common problems. This organization has to date brought forth many interesting papers based on research in Jewish music. The organization sponsored a "Conference on the Status of Synagogue Music in America" in June 1941, at which the problems of synagogue music were discussed by professional Jewish musicians, composers and laymen.

At this time there are many Jewish musicians all over the world who are working

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

toward the creation of a Jewish musical idiom. Many works in all forms, large and small, have been created, published and performed by major musical organizations throughout the world. Cornill; *History of Musical Instruments* and *The Rise of Music in the Ancient World,* Curt Sachs; *Music In Western Civilization,* P. H. Lang; *Medieval Hebrew Minstrelsy,* Lowe; *The Music of the Pentateuch,* S. Rosowsky; *Sabbath in Music,* A. W. Binder; *Quartel Harmony,* Joseph Yasser. —A.W.B.

**Jew's harp, Jew's trump.** See MUSICAL INSTRUMENTS.

**jig.** See gigue.

**jigger, jolly.** *Cer.* Machine for making round or oval ware. See CERAMICS I.

**jig-tunes.** See AMERICAN NEGRO LITERATURE.

**jiki** (Jap.). Name for porcelain.

**jiku** (Jap.). Ornamental knobs at each end of the round stick on which Japanese paintings are mounted and rolled.

**jimotsu** (Jap.). Attributes (q.v.).

**Jinghizid architecture.** See ISLAMIC ART.

**Pögan art.** See JAPANESE ART.

**joint.** *Book.* The term is applied in several ways in bookbinding. (1) The complete hinge of the cover (see French joint). (2) Strips of various materials attached to the fold of end papers, and first and last sections, etc. (3) The groove only, as opposed to the whole of the hinge. (4) A mend. —H.E.S.

**joist.** A horizontal member, as a timber, forming part of the structure of a floor or ceiling.

**jolly, jigger.** *Cer.* Machine for making round or oval ware. See CERAMICS I.

**jongleur.** See MEDIEVAL MUSIC.

**jota.** A national dance of Spain; one of the classic Iberian dances. In its present form, it is perhaps closer to its origin in peasant dance than are the others of its group. The movement is strong, rapid, and staccato in quality with a certain rustic stiffness and angularity. It is danced in four/four meter by a man and woman, giving rollicking, pantomimic suggestion of simple courtship. The rhythmic patterns of the dance and the castanet accompaniment form a fast, syncopated counterpoint to the melody, which is slower and paradoxically melancholy in mood. —J.G.

**jubilus.** See MEDIEVAL MUSIC.

**jug.** A deep vessel with a narrow mouth and a handle.

**Jugendstil.** The name given to the style of a movement for a renewal of the applied arts and architecture in Germany in the last decade of the 19th cent, and the early 20th cent. The name is taken from the magazine *Jugend* (first published 1896 in Munich). The illustrations, decorative designs, etc. of this magazine—reminiscent of A. Beardsley, Edvard Munch—are typical for the *Jugendstil.* The corresponding style in England and France is known under the name of *Art Nouveau,* in Italy as *Stile Liberty,* the names being taken respectively from the shop *Art Nouveau* opened by the Hamburg art dealer S. Bing 1896 in Paris and from Liberty's of the Strand.

In its beginning this new movement was closely connected with the visual arts, as evidenced by the fact that many of the architects originally started as painters (e.g. Peter Behrens, R. Riemerschmid, Bruno Paul, Bernhard Pankok, Henry van de Velde [a Belgian who exerted great influence upon the German movement]). The interiors or exteriors designed in the early phase, such as August Endell's facade of the Elvira studio in Munich (1898), look somewhat like enlarged decorative drawings transferred into different material (cf. drawings or etchings by Klimt, Max Klinger).

The *Jugendstil,* which is greatly indebted to the work of William Morris and his followers in England, prepared the way for the modern style in architecture and industrial design. Those among the moderns who ridicule the *Jugendstil* for its elaborateness forget that it is due to the efforts of this movement that the artistic qualities of good workmanship and the aesthetic values of materials and of textures were rediscovered and recognized. The consideration of the use and function of materials is the first step towards an objectivism (*Sachlichkeit*), which solves problems of design in architecture and industrial production by reference primarily to the functions involved and the materials available and best suited to the functions. See GERMAN ART; art nouveau; also E. Michalski,

# K

**kabe-e** (Jap.). A mural. *Kabe*—wall; *e*—painting, wall-painting.

**Kabuki drama.** See THEATRE.

**kachina, katcima.** Supernatural beings, hundreds in number, whose cult is widespread among the Pueblos of the Southwest but strongest among the Hopi and Zuñi. Their home is in the San Francisco mountains, according to the Hopi, whence they come to visit the villages for six months to dance, sing, bring presents to the children and, primarily, to take to the gods the prayers of the people for rain and fertility. A long succession of ceremonies takes place during their presence in the villages. The term also applies to the masked dancers who impersonate the kachinas and to the dolls made to represent them. —H.G.

**kacho** (Jap.). A painting composite including rock, tree, flower and bird.

**kakemono** (Jap.). Literally, "hanging thing". A painting, or example of calligraphy, mounted with brocade margins incorporating a round stick at the bottom on which the painting can be rolled up when not in use, and a small stick at the top by means of which the painting can be hung on the wall. —J.A.M.

**kakemono-e** (Jap.). A long vertical woodblock print, about 28 by 10 inches; or a horizontal print of unusual size.

**Kakiemon ware** (Jap.). Porcelain made by the potter Kakiemon.

**kakihan** (Jap.). A hand-written seal mark; a monogramlike signature.

**kalamaika.** A lively Hungarian dance in 2/4 time.

**kalamkar.** The Persian name for those gay prints was *kalamakari.* A printed cotton cloth from India.

**kama** (Jap.). An iron kettle with a removable cover in which the water is boiled for *cha-no-yu* (q.v.).

**Kamakura art.** See JAPANESE ART.

**Kamakura-bori** (Jap.). Carved wood thickly lacquered in red or black. A lacquer style particularly favored in the city of *Kamakura.*

**Kamares ware.** See Aegean vases.

**kamarienskaya.** The kamarienskaya dances form one of the four fundamental classes of Russian national dances. They are the romantic group as contrasted to the chorovody, the trepak, and the kasatschy. The kamarienskaya are solos, the dances of the bride-to-be, in which she describes her romantic anticipation of wedded bliss. The dances are usually divided into two phases. The slow and flowing movement of the first changes in the second to a figure of increasing speed and excitement, ending in an abrupt climax symbolic of the meeting with the groom. —J.G.

**kamashiki** (Jap.). A metal or pottery stand on which the hot water kettle may be placed when and if removed from the fire during *cha-no-yu* (q.v.).

**kami** (Jap.). Paper.

**kamptulicon.** An early floor covering material using India rubber to bind together particles of cork.

**kan** (Jap.). A pair of open metal rings by which the kettle may be removed from the fire, during *cha-no-yu* (q.v.).

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**kanagai** (Jap.). See raden.

**K'ang-Hsi dynasty porcelain.** See CERAMICS II.

**Kanga school** (Jap.). A style of painting which, as the Chinese word implies, was deliberately Chinese in manner.

**kangwa.** See JAPANESE ART.

**Kano school** (Jap.). School of painting after the style of Chinese painting. See JAPANESE ART.

**kanon.** See Eastern chants.

**kanshitsu** (Jap.). A lacquer technique whereby cloth is saturated with lacquer and modeled over armatures to produce sculptural forms. In vogue in China and Japan in the 8th and 9th cent. Sometimes called "dried lacquer" work. —J.A.M.

**kaolin** (Fr. fm. Ch.). A pure white clay (hydrous silicate of aluminum) used in the manufacture of porcelain. See China clay; CERAMICS I.

**kapists.** See POLISH ART.

**kap kap.** A type of ornament common in some parts of Oceania consisting of incised tortoise shell mounted on polished sea shell. See OCEANIA, THE ARTS OF.

**karakul** (fm. Kara Kul, lake in Pamir, literally black lake). A broad tail sheep of hardy breed. Brown wiry fur on adult sheep. New born lamb glossy black. The term is applied to fabrics made in imitation of this fur. —G.W.R.

**kara-ori** (Jap.). Literally, "Chinese fabric", referring to the sumptuous imported brocades; any heavy, elaborate brocade.

**karashishi** (Jap.). The "Chinese lion" motive.

**Karatsu yaki** (Jap.). Pottery made in the province of Hizen.

**kara-yo** (Jap.). See JAPANESE ART.

**Karminian.** Another name given to the Khilim rug.

**Karok.** See California Indian art.

**kasatsky.** A group of Russian national dances, closely interrelated and distinguishable from the other three major groups, chorovody, trepak, and kamarienskaya, by their dramatic content and the fact that they are always performed by one couple only. These dances are devoted to a spirited portrayal of courtship. The man's role is more vigorous and technically difficult than the woman's, beginning quietly, but increasing in power and speed to a tremendous climax. Like most Russian folk-dances, the kasatsky stress and depend upon the technical ability and inspiration of individual dancers. —J.G.

**Kashan ware.** See ISLAMIC ART; PERSIAN ART.

**kashi.** (Ar.). Glazed tile inlay used for brickwork. See ISLAMIC ART.

**kashira** (Jap.). An ornamental metal cap on the upper end of a Japanese sword handle.

**kata-kiribori** (Jap.). Incised chiseling, in which the lines imitate brush strokes.

**katana** (Jap.). Sword with a single cutting edge.

**katcina (kachina) niche.** In southwestern archeology: A niche, often found in ceremonial chambers, seemingly used during some ceremonies for the depositing of certain masks, etc. when not in use by the participants. Among the Hopi this niche is called the Katcina kihu or house of the Katcinas. —J.M.M.

**kbogan.** See FLOWER ARRANGEMENT.

**keep.** See castle.

**Keet Seel** (Navaho, broken pottery). An Anasazi cliff village built in a cavern in the Laguna (or Segi) Canyon of north central Arizona. It contains more than 150 rooms and circular subterranean kivas. It is now a part of the Navaho National Monument. See Pueblo art. —H.G.

**kesa** (Jap.). A priest's special outer robe in the form of a rectangle which is thrown over the shoulders and caught at the left shoulder with a single cord. —J.A.M.

**kettledrum.** See MUSICAL INSTRUMENTS.

**kettle-stitch.** *Book.* In some hand-sewn books and some sewn by machine the stitch at the head and tail—or top and bottom—of each section joining it to those on either side. In other cases the needle holes nearest top and bottom. —H.E.S.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**key** (Fr. *tonalite;* Ger. *Tonart;* It. *tonalitá*). *Mus.* A term denoting a series of tones or scale and harmonies that center on a specific note. The term also applies to the mechanism of various musical instruments. Although often used interchangeably with "scale" the substitution is not strictly correct. A scale consists of a melodic succession of tones whereas the "key" as reference to the tonal series and the chords connected with them. Tones foreign to the key, however, may be introduced without disturbing the tonal center. The key of a piece is indicated at the beginning of a composition by placing the proper signature of sharps or flats at the beginning. In classical compositions the last bass note is likewise the key-note.

Historically the major and minor keys of to-day are an outgrowth of the older modes. Through the use of Musica Ficta notes extraneous to the mode were gradually introduced and in time (17th cent.) the modern key feeling was established. There are twelve major and twelve minor scales. The key of the relative minor has the same signature (G and e minor) and that of the Tonic minor is built on the same key-note (C and c minor). Keys bear a close relation to each other and passing from one these tonalities to another is termed modulation. The common circle of fifths exemplifies the simplest of these modulatory relations. There are many other connecting links between these different tonalities which are revealed by a study of modulation. The tendency in many contemporary scores is to reject those commonly accepted by using two or more tonalities (polytonality) while others have used a scheme based on the twelve-tone scale which results in no tonality (atonality).

Although there were others who were vitally interested, Bach's *Well-Tempered Clavichord* is regarded as the turning point toward establishing the tempered scale rather than the mean-tone system formerly in use. The mean-tone tuning prevented the use of keys beyond three sharps or three flats as they would be out of tune. Modulation was, of course, restricted. In many of the compositions of the Bach and Handel period the signatures will be found to contain a flat or sharp less than in those of the present era. This is evidence of their connection with the modal era which was largely in disuse but which still influenced the composers. In modern scores based on the chromatic scale or twelve-tone system, signatures are very often omitted to simplify the reading for the performer and the sharps and flats added to the notes that require them. For a consideration of *key* in relation to the mechanics of an instrument such as the piano, organ, etc., reference may be made to these subjects. See idiom A(5), B(2), (3), (4), C. —J.V.H.

**key-block.** A wood-block (q.v.), on which are cut contour lines only. This block, when applied to a print, outlines all color areas with a black line. —J.A.M.

**keyboard.** *Mus.* Row of keys (pianoforte, organ).

**key-note.** See idiom A (2).

**key novel.** See NOVEL, THE.

**key pattern.** A fret pattern similar to the Greek fret but after the form of a typical oriental key to a lock.

**key plate.** *Etch.* Usually the blue or black plate in multiple plate color acquatint work. This plate carries most of the outlines and is used to offset onto the other plates. —K.K.

**key ring.** See JEWELRY.

**keystone.** The voussoir at the crown of an arch, regarded as binding the whole.

**khan.** (Ar.). An open or vaulted court with one or two stories of small rooms surrounding it. See ISLAMIC ART.

**khanaqah.** (Ar.). A cult-building (usually) of mosque type with subsidiary courts surrounded by rows of cells. See ISLAMIC ART.

**khatt.** (Ar.). Calligraphy. See ISLAMIC ART.

**Khilim.** Written also Ghileem, Kilim, is a flat stitched rug without a nap and woven without a shuttle by the nomads in Turkish Kurdistan and the surrounding country. This rug is alike on both sides. See TAPESTRY. —B.E.J.

**Khmer art.** See INDIAN ART.

**kickwheel.** *Cer.* Foot-driven throwing wheel. See CERAMICS I.

**Kidderminster.** A place in the British Isles famous for carpet made without a nap.

**kilims in Poland.** See POLISH ART.

**kiln.** An oven or furnace for baking, burning, or drying, as for bricks, pottery, or lime-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

stone; may be heated by gas, oil, electricity, wood or coal.

**kinesthesia.** Consciousness of one's own muscular sensations in terms of the amount of effort and speed demanded in the performance of any act. It is motor observance. —M.N. H'D.

**kinesthetic sense** (muscle sense). The special sense employed in the perception of the sensations from active muscles, tendons, and joints. Just as the visual sense conveys sensations of sight to the brain, so does the kinesthetic sense, in combination with pressure sensations convey impressions of the body in activity and in states of equilibrium and rest. Upon them are based judgments of force, range, and duration of movement. Knowledge of the positions of the body and its parts in relation to one another and to space are also ascertained from kinesthetic sensations. And further—ideas concerning the form and solidarity of objects have a kinesthetic basis. The distinguishing characteristic of muscle sensations by which movements are known are time (duration) and stress (force) whose ratios determine the rhythmic structure of all muscular activity (see rhythm). Therefore, kinesthetic is fundamental to rhythmic perception. A keen and reliable kinesthetic perception is essential to all effective uses of the body and is an invaluable endowment to a dancer. —M.N. H'D.

**kinetic sculpture.** See SCULPTURE.

**kingly pose.** A formal pose, seen in East Indian art, whereby the right foot is raised to the seat level and the right arm rests on the raised knee. —J.A.M.

**king's yellow.** See orpiment.

**kinji** (Jap.). A lacquer technique. A plain gold ground.

**Kinkazan yaki** (Jap.). Pottery made in Mino province.

**Kinnor** (Heb.). A small harp. See JEWISH MUSIC.

**kinoko** (Jap.). The fungus (q.v.).

**kira-e** (Jap.). Woodblock prints with backgrounds of powdered mica.

**kirikane** (Jap.). (1) A painting technique. Gold-foil cut in hairline strips and applied to the painting, especially to represent the patterns on fabrics. (2) Also a lacquer technique. Gold or silver-foil cut in small rectangular pieces and applied to lacquer to make an all-over pattern. —J.A.M.

**kirin** (Jap.). Fabulous deerlike animal with single horn, similar to the unicorn. See chi'i-lin.

**Kissi, art of the.** See AFRICAN NEGRO ART.

**kithara.** See MUSICAL INSTRUMENTS.

**kiva** (Hopi). In southwestern archaeology: A chamber especially constructed for ceremonial purposes. Two general types are recognized, (a) circular, and (b) rectangular. The circular group falls into two major divisions, the ordinary-sized chambers which are frequently termed clan kivas, and the superceremonial structures, or great kivas. It is thought by many southwestern archaeologists that the circular kivas, of the ordinary-sized group, represented a survival of an older original type of dwelling. The round form of kiva reached its greatest development in the nuclear portion of the Pueblo region, in the Great Period of prehistoric Pueblo construction. The rectangular form of kiva is believed to be of later origin in the Pueblo system of building. —J.M.M.

**Kiyomizu-yaki.** (Jap.). Pottery made in Kiyomdsu, in Kyoto.

**kiyose-ho** (Jap.). The technique of forming a statue from several sections of wood instead of carving it from a single piece.

**Klaviatur-Sphaerophon.** See electrical instruments.

**knei** (Ch.). A shape characteristic of some Chinese stone tablets; i.e., circular at the top and square at the bottom.

**knitted rugs.** Made by strips of material cut and sewn together endwise and wound into balls of string to be knitted into floor pieces.

**knots.** The yarn which forms the substance of a rug is tied around the warp threads, forming knots. The texture of the carpet depends upon the fineness of the knots. —B.E.J.

**knots, single warp.** The strands of yarn are wrapped all the way around a single thread of warp, crossed at the back and the ends brought to the front, one on either side. It is tied on alternate threads. As in other

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

weaves, after each row of knots has been tied, one or more weft threads are put in. This knot technique produces smooth diagonal lines instead of perfectly even vertical lines. This knot appears in the early Spanish carpets and rarely in the Oriental rugs. See *European and American Carpets & Rugs*, C. B. Faraday. —B.E.J.

**ko** (Ch.). Generic term for arrowheads, knives, daggers, etc.

**ko** (Jap.). See *vajra*.

**kobako** (Jap.). A utensil for cha-no-yu (q.v.). See *kogo*.

**koban** (Jap.). A vertical woodblock print slightly smaller than a *chūban* (q.v.).

**koboshi** (Jap.). A receptacle for waste water, used in *cha-no-yu* (q.v.).

**Kodo** (Jap.). Lecture hall of a Buddhist temple.

**koen** (Jap.). A term used to denote "high distance" in a painting; mountains painted as though seen from below.

**Koenig sensation curves.** See COLOR.

**kogai** (Jap.). A pair of skewers, sometimes called hairpins, inserted in the scabbard of the "long" sword.

**kogo** (Jap.). A small box of lacquer or pottery in which are kept the pellets of incense used in *cha-no-yu* (q.v.).

**kohai** (Jap.). Japanese word for halo.

**kojiri** (Jap.). An ornamental cap fitted over the lower end of a sword scabbard.

**koka-ryokugo** (Jap.). A lacquer technique in which the object is first coated with layers of red and of green lacquer and then carved in a pattern of crimson flowers among green leaves. —J.A.M.

**kokechi** (Jap.). Japanese word for the technique of tie-dyeing.

**kondo** (Jap.). Gilt-bronze.

**Kondo** (Jap.). Literally, "golden hall", the hall of worship in a Buddhist temple.

**kontakia.** See eastern chants.

**Korai ware** (Jap.). Korean pottery ware of the *Korai* dynasty (918-1392).

**koro** (Jap.). Incense burner.

**kose.** See JAPANESE ART.

**Kosobe yaki** (Jap.). Pottery made in Settsu province.

**koto.** See MUSICAL INSTRUMENTS.

**koto-buki** (Jap.). The Japanese word for the Chinese character, *"shou"*, meaning long life and happiness. Often used as a decorative motive. —J.A.M.

**ko yao** (Ch.). Chinese pottery ware of the *Sung* dynasty.

**kozuka** (Jap.). Small knife, inserted in the side of the sword scabbard.

**krakowiak.** See cracoviac.

**krater.** See crater.

**kremnitz white.** See white lead.

**k'ssu.** See TAPESTRY.

**ku** (Ch.). Sacrificial bronze vessel, beaker-shaped, for holding sacrificial wine.

**k'uan** (Ch.). Signature or colophon of an artist.

**kuang** (Ch.). Sacrificial bronze vessel, sometimes three-legged, with handle at side and large open spout. When the cover is in place, the spout is covered and the vessel then appears like a quasi-animal form with curled tail (handle), long neck (spout), and horned head, which is a part of the cover. —J.A.M.

**Kuangtung yao** (Ch.). Chinese pottery ware of the *Sung* dynasty.

**kuan yao** (Ch.). Chinese pottery ware of the *Sung* dynasty.

**kuei** (Ch.). A ritualistic jade tablet, thin and rectangular with a pointed end, which is symbolic of the East and used as a symbol of authority. —J.A.M.

**kuei** (Ch.). Sacrificial bronze vessel, with two or four handles at side usually, and a base. Used to hold sacrificial food.

**kuei pi** (Ch.). A jade form which combines a disc (*pi*) with a tablet (*kuei*). It is said to be symbolic of the sun, moon and stars, and is used ritually. —J.A.M.

**Kufic script.** See ISLAMIC ART.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**kulepa.** See MUSICAL INSTRUMENTS.

**kuljak.** This Esthonian national dance, like others of that country, reflects more strongly than most folk-dances the primitive religious significance of dance. It is performed by men and women in circular formation around a fire. The dancers circle with joined hands, walk in promenade by twos, or dance singly with small angular movements. The dance is accompanied by harp music closely related in meter and tempo to the Hungarian czardas (q.v.). —J.G.

**Kulturkreis** (Ger.). The social-cultural complex; a concept frequently employed in ethnographic approaches to the study of art.

**kung pi** (Ch.). A precise and meticulous method of painting in the academic style.

**Kunst For Varer.** See SCANDINAVIAN ART.

**Kunstforeninger.** See SCANDINAVIAN ART.

**Kunstnärsforbundet.** See SCANDINAVIAN ART.

**ku-pi** (Ch.). A *pi*, q.v., decorated jade with a grain or "millet" pattern.

**kurikata** (Jap.). Oval knob near the top of a scabbard with a channel opening in the side through which a cord passes (*sageo*, q.v.) to fasten the scabbard to the belt or to fasten the sword in the scabbard. —J.A.M.

**Kushan art.** See INDIAN ART.

**Kusuura yaki** (Jap.). Pottery made in province of Buzen.

**Kutani yaki** (Jap.). Pottery made in the province of Kaga.

**Kwakiutl art.** See Northwest Coast Indian art.

**kylix.** See cylix.

**kyogen.** See JAPANESE ART.

**kyokechi** (Jap.). Ancient name for *itajime* (q.v.).

**kyrie.** See MEDIEVAL MUSIC; Mass.

# L

**Lac.** A natural organic red dyestuff usually has been given this name, and it is also called "lac lake" and "Indian lake". It comes from the resinous secretion of the larvae of the *Coccus lacca* which lives on certain trees native to India and the Far East. This is similar to the secretion from which seed lac or shellac is obtained. It is similar, also, in composition and color to the carmine lakes from cochineal, but lac is slightly duller in tone and somewhat more stable. It seems to have been used more largely in the East than in Europe, but became moderately familiar to Western painters during the Middle Ages. —G.L.S.

**lace.** Hand made or *real lace* exists in two main classes: (1) needle point or point lace made by the needle; (2) Bobbin or pillow lace made with bobbins and pins on a pillow. Machine made lace sometimes imitates hand made lace—sometimes produces original designs producing the effect of hand made lace —or produces an entirely unique effect. It is always possible to detect the difference between real and machine made lace. Sometimes a fabric is made with a combination of machine work and hand made work.

Intricate cords, fringe and nets fashioned of fibers of flax, hemp, and wool are the forerunners of lace. The priests of Egypt sometimes cut holes in gazelle skins making a lace effect. Peruvian laces show diagonal serrated stripes with fretted key devices, chevrons, crosses, roundels, squares, lozenges and representations of the puma, the duck and the fish. These laces are made of acuna, wool and fibers of the maguey, a species of cactus plant. There are a few specimens of lace dating from the Byzantine Emperor Justinian. All pre-Renaissance lace consisted of drawn work, cut work, darned work and macrame. Some of the stitches used are called *punto avora, punto saracen* and *point mouree.*

Lace making flourished in the Grecian Archipelago and it is from these sources that lace was first introduced into Venice during the Byzantine period. About the year 1530 the Venetians abandoned all foundation material and relied on the needle to create the fabric. The first real lace was the fine Italian needlepoint lace we know as **punto in aria.** The design took on floral forms with curved lines.

**Reticella** was the earliest of needlepoint laces. It was a development of cut work and drawn work. Brides and picots were introduced at intervals. The late development of reticella show circles and curved, free flowing lines in the design. A pattern book of laces was printed in Venice in 1560 which tends to establish Italy's claim to have been the first European country to develop the making of true hand-made lace. Flanders has for years contested Italy's claim as the originator of the European industry.

At the same time lace-making was developing in Italy it was developing independently in Flanders by an entirely different process, employing pillow, bobbin, and pins. Flanders lace industries began to flourish at the end of the 16th cent. Mixed laces in both countries were of a later date, after each country had copied the work of the other.

Pillow bobbin and fringe lace all developed from plaited fringe work. The pattern is developed thru crossing, plaiting and braiding threads. The pillows used vary in shape and mechanism. The design drawn on parchment must not measure more than the circumference of the pillow. The lace maker tosses her bobbins about, braiding the threads which hang from the top of the pattern fastened on the pillow. As one pattern ends

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

another commences. Pins are used to fasten the threads in place on the pillow. The pins are removed as the pattern progresses.

From 1540 to 1590 lace showed geometric forms set within square or crossed and radiating line devices, in a very open fabric. No brides or reseaux were used. From 1590 conventional floral and even human and animal forms and slender scrolls in a tape-like texture held together by brides appear. From 1620 to 1670 the development of long, continuous scroll patterns with reseaux and brides accompanied in the case of needle made laces with an elaboration of details (coordinated with massings of picots). From 1650 to 1700 the scroll patterns gave way to arrangements of detailed ornamental details. From 1700 to 1760 more important schemes or designs were made into which were introduced naturalistic rendering of garlands, flowers, birds, trophies, architectural ornament and human figures. From 1760 to 1800 small details lognets, sprays of flowers, single flowers, leaves, buds, sopts, were adopted, and sprinkled over meshed grounds, and the character of the texture was gauzy and filmy.

Different countries developed distinctive designs: *gros point* de Venice in Italy; *meclin* in Flanders; heavy *blonde* in Spain; *point d'Alencon* and *chantilly* in France; *Honiton* in England; *Carrick ma crosse* and *Irish crochet* lace in Ireland. —G.W.R.

**lacing.** *Book.* When the cords or tapes—slips—are passed through the holes in the boards to attach them to the book.

**lacing course.** In masonry: The term applied to a horizontal band of stone placed in rubble or rough walls to form a longitudinal line.

**lacquer.** Numerous synthetic resins are grouped under the heading, lacquer, but in the arts the term still keeps its traditional meaning as the specific name for a natural resinous exudation from the tree, *Rhus Vernicifera* DC. This is most common in China and Japan but there are lacquers from Burma, Indo-China, and Formosa. The lacquer is extracted as a sap and seems to have been used directly as a coating material for various objects of fine workmanship. Precise methods of application have been largely kept as secrets, and possibly the poisonous nature of this sap has prevented it from gaining a wider use. Its affect is somewhat like that of ivy poisoning. As a film it has unusually stable characteristics. It hardens in the presence of moisture, does not become brittle, and can be highly polished. When thoroughly dried, it is unaffected by acids, alkalis, or alcohol, or by heat up to about 160 degrees C. —G.L.S.

**la ch'in.** See MUSICAL INSTRUMENTS.

**lacquer print** (so-called). A broadsheet, classified as a print, but painted in parts to represent a lacquer medium.

**lacquerware.** A technique peculiar to the Orient, whereby the sap of the poisonous sumac tree is used as a painting medium in the fine arts. In the crafts it is used over a wooden base producing a surface of permanency and great beauty, with all the aspects of the painter's art.

The lacquerer is nearly equal in rank to the painters of the Orient. For further details see the following:

**laksana.** See INDIAN ART.

**La Libre Esthetique.** See art nouveau.

**lamé.** A fabric shot through with metal threads or having a brocaded pattern in metal with silk or rayon.

**lamp black.** Among the various carbon blacks, this is probably the finest in texture. It is made from the condensed smoke of burning oil, tar, gas or resin. Such black pigment was known in ancient times and has had a continuous use since then. —G.L.S.

**lancet window.** A high narrow window (without tracery) with a sharply pointed head.

**ländler.** A Styrian peasant dance in 3/4 time; a kind of waltz.

**land planning.** See CIVIC PLANNING.

**LANDSCAPE ARCHITECTURE.** Landscape architecture, of ancient lineage, had its rise when man first began to modify his intimate surroundings for more practical use and, shortly afterwards, for more pleasing arrangements. No doubt aesthetic considerations in the beginning were correlated with primitive religious concepts; but the relative precedence of personal desire for aesthetic appearance as against that of religious influence is not known, and the preponderance of one factor over the other can only be surmised by comparative study of the contemporary arts. The names of the earlier landscape architects have not been preserved, although the evidence of thir handiwork is well established by archeological research.

At first the ordered arrangement of ground about the habitations of man was purely an expression of individual taste: for the earlier adepts in development of ground for better use and enjoyment were part of the retinue of some individual whose land, because it was unplanned, had been found both inconvenient and unproductive. But as time went on, as in all of the fine arts, certain basic principles became the common knowledge of all employing the art.

Probably the highest development of the art of landscape architecture, in the sense of its most widespread contemporary use, was in Italy during the Renaissance. Many examples of this period exist today, but most people who visit them understand them only from the background of modern experience. The gardens are beautiful, and as such the power of their beauty obscures the fundamental fact that they were primarily useful to the builders. Since appreciation of their original utilitarian purpose has been largely lost, and because they are a source of visual pleasure to the visitor, the art which brought them into being is incorrectly judged to be concerned only with beauty. Equally unfortunate, it is also assumed to be concerned only with large properties because the Italian villas of the Renaissance were large.

In evaluating the place of the landscape architect in our present-day social structure, it is peculiarly pertinent to observe that when the outstanding works of landscape architecture were achieved in Italy, and somewhat similarly in France and England, it was the time when the individual of force, character, and position dominated society. Public service as we know it did not exist; there was only the most rudimentary concept of the State as separate from the powerful individual. This circumstance was precisely set forth by Louis XIV: "I am the State." The practitioner of any of the fine arts at that time could exist only by the pleasure and grace of powerful patrons.

With the decline of the power of monarch and nobility, and the rise in power of the people, the idea of public service as well as service to the public came into being; and at the same time the place of the architect, doctor, lawyer, and landscape architect as independent and free agents related to society became fixed. The earliest example of landscape architecture conceived as a public improvement, carried forward to completion as such, and financed from public funds, was Central Park in New York City. Earlier examples, such as the squares and greens of Colonial settlements were not founded on this philosophy, but were outgrowths of community necessity or grants made by the great land development companies for pasturage or other specific land uses other than that for park purposes as they are now used. The circles and plazas of the L'Enfant plan of Washington were in part military,—artillery emplacements for efficient quelling of rebellion. Today, landscape architecture is still one of the arts of civilization, assisting man in his effort to modify his surroundings for more efficient and orderly use, and to bring to these revised or corrected surroundings such pleasure as may be compatible with the situation. The landscape architect as an individual rendering service to the public is now as interested in small properties as in large

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

ones. Wherever there is a problem of bringing ordered arrangement to a large tract or a small parcel of land, the landscape architect can make his contribution to its development, and in this he is a working member of society.

With the growth of the power of the people, supplanting the functions of the monarch, it is worthy of note that great current examples of landscape architecture in the democracies throughout the world have taken the form of national parks and national monuments, national forests, extensive metropolitan and city parks and parkways, landscape improvement of public highways, landscape development of subsidized low-rent housing, and other similar works which are for the benefit of the community as a whole. Modern landscape architecture serves democratic ends; for this reason work comparable with Versailles in intensive development has not been done in recent years. In breadth of conception and monetary value, however, several of the larger public works projects executed in this country exceed those of kings and nobles, and in respect to man-hours of work there is little doubt that some WPA projects exceed the undertakings of Louis XIV.

The work of the landscape architect, in the public field as well as in relatively smaller problems for the private individual, is first of all planning land areas for specific uses, and subsequent development is secondary to the primary allocation of land. In the preservation of natural conditions, construction and planting are minimized when they cannot be avoided. The landscape architect, whose training is based upon land use, is always conscious of the land; and for this reason it should be remembered that, while of itself a private residence project may be a relatively small undertaking, the training and experience brought to bear upon it by a competent landscape architect embrace consideration of certain aspects of town and regional planning, transportation and traffic, public service facilities, and zoning, and may well include problems of erosion control, soil conservation, reforestation, and water-shed preservation, in addition to the specific problems of the site, —all because the landscape architect is conscious of the fact that all the surface of the earth is continuous, and that land planning which fails to recognize this fact cannot be completely successful. Herein lies a fundamental difference between landscape architecture and civil engineering or architecture.

A concise statement of the several types of work with which the landscape architect may be concerned appears in the following statement prepared by the American Society of Landscape Architects:

(1) *GENERAL AND BROAD-SCALE PLANNING: General Considerations External to a Definitive Project.*

Selection of a site to conform to predetermined requirements, accompanied by a report upon its relation to the surrounding region and an estimate of the probable effect of the project upon the region.

Professional work would include: Reports on transportation and traffic; recommendations for new planning legislation or for amendment of existing planning legislation (including zoning); appraisal of recreational and social facilities; public service facilities in respect to their adequacy; financial structure of the region affected by the project; cooperation with local planning authorities; and coordination with local physical development programs and local social or economic activities.

(2) *LAND USE PROBLEMS AND GENERAL LAND DEVELOPMENT PROGRAM.*

Problems of a *regional significance*: Allocation of land for economic, recreational, social, or scientific purposes such as agriculture, industry, housing, erosion, erosion control, wildlife conservation, reforestation, parks, parkways, and park system of national, state, regional, or municipal character.

Professional work would include: Reconnaissance investigation, formation of programs, drafting of legislation, and coordination of the various levels of government, etc.

Problems of *land use upon a specified area*: Allocation of land within a limited area in conformity with the purpose, dedicated to some form of public use or benefit, such as recreation, reforestation, wildlife restoration, development of area to demonstrate one or more scientific concepts, and allocation or development of outlying land about a given project for purposes of "buffer" or protection.

Professional work would include: Determination of the various types of land uses in which an area should be divided; general locations of special improvements or alterations; recommendations as to extent, character, and specific use of improvements, accompanied by estimates, reports, outline spe-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

cifications, and contractural conditions if necessary.

(3) *SITE PLANNING AND DEVELOPMENT.*

Location of buildings and other structures in relation to topography; drives and walks for vehicular and pedestrian circulation, with parking spaces; control of ground forms through grading; location of recreational areas, playgrounds, athletic fields, and their necessary facilities and equipment, lawns, and planting areas; drainage, irrigation, and their appurtenances; structures incidental to landscape development, such as swimming pools, wading pools, shelters, etc.; and general or specialized planting arrangements pertinent to the development. The work of the landscape architect in site planning also includes the planning of parks and other public properties, institutional properties, land subdivisions, housing projects, cemeteries, and private properties.

Professional work would include: Usual preliminary studies and reports and final working drawings, specifications, preliminary and final estimates, material schedules, contract documents, and supervision of construction. Landscape architecture draws upon the specialized fields of technical knowledge such as geology, agriculture, and particularly its handmaiden, horticulture, and upon architecture and engineering for incidental and necessary supplemental data, but primarily it is a field of its own with established and ever-accumulating basic principles necessary for the planning of land for human use and enjoyment.

The materials of landscape architecture are for the most part natural,—earth and water forms in their infinite variety, and living plants,—but include a limited number of processed materials. Both plants and processed materials must be either climatically adapted or weather-enduring. A completed project in landscape architecture is not finished when the designer ends his work; it must mature over a period of years, the number required depending upon the character of the development. In this, landscape architecture differs from all other arts, for its works—unlike those based on processed materials—do not begin their decline upon completion. There is a general misconception that the work of the landscape architect primarily deals with plants and horticultural problems. On the contrary, plants and planting are but the last step in the development of any project, and must always follow problems dealing with location of buildings, grading, drives, walks, etc. Of course, vegetation is an important element in landscape composition, but must be coordinated with other elements of design and construction to complete the final effect.

Inasmuch as the elements comprising landscape architecture are as variable as its terrain and its materials, it cannot be defined by unbreakable rules, and for this reason it is often defined to suit the particular limitations of its application. Most of these definitions overlook the fact that it is primarily concerned with three dimensions, and also, that substitute terms for landscape architecture (and the landscape architect) are specific limitations rather than a statement of general principles. There is no approved definition, but in lieu of an authorized version it may be stated that: Landscape architecture is the planning of land by allocation into ordered arrangements for various purposes and its subsequent development whereby economic, social, physical, and aesthetic values are simultaneously recognized and proportionally emphasizbed according to the requirements of the problem for the purpose of deriving maximum use and human enjoyment.

Landscape architects are found practicing their profession in private offices, and in many public offices at all levels of government,—some under titles which give no clue to their professional training. A large number of city or town planners are trained landscape architects, as also are many government officials in charge of broad-scale planning and in the fields of recreation and conservation. The landscape architect, whether in private practice or in public service, looks upon his work as a profession, and therefore is not concerned with speculative profit on labor or materials. His method of rendering service follows a rigid code of accepted practices, and is analogous to that of the medical or architectural professions. The official organization sponsoring landscape architecture in this country in which qualified professional landscape architects may become members is the American Society of Landscape Architects, founded in 1899.

In a current dictionary of fine arts the influence of the modern attitude should be particularly noted. Most landscape architects consider their profession to be fully in conformity with today's demands since their efforts are directed toward public wel-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

fare as well as for the service of the individual. However, those who are drawn to the current trend believe that modern landscape design must express itself and be inseparable from modern architecture in spirit, technique, and development, and that the design of gardens should change to reflect the contemporary spirit rather than to cling to precepts of the past, many of which are now archaic or sentimental. But landscape architecture is both conservative and radical simultaneously. In its larger works, where extensive units of water, vegetation, broad sweeps of land and sky are the elements of a composition, it is to a great extent at the mercy of its materials. To conserve and preserve the natural compositions or to reconstruct them for posterity in perpetuity is still a radical concept that is not fully appreciated. In areas of smaller extent a designer may impose his will and design according to style. Competency of design is judged in the final analysis as to economic values, and for this reason recent work strives for low operating costs; similarly, older work is revised to make it economically maintainable and as pleasurable as may be compatible with economic limitations. See CIVIC PLANNING.

*Glossaries*: Terms used in landscape architecture are drawn from the allied fields of architecture, engineering, construction, and from subdivisions of agriculture such as botany, forestry, horticulture, etc. The terms borrowed are defined in the references to these fields and practically all are in one of the unabridged dictionaries. A general or complete glossary of the terms applicable to landscape architecture has not been published. Specialized glossaries of limited application are:

*Housing*: "A Glossary of Landscape Terms", prepared by the Sub-committee on Landscape Work for the Central Housing Committee, Washington, D. C., 1942.

*Horticulture*: *The Complete Garden,* Taylor and Cooper, N. Y., 1923.

*Botany*: The botanical manuals contain glossaries for botanical subjects and works devoted to a specialized plant group contain abbreviated glossaries suitable for their purpose. —W.A.S.

**language of art.** A metaphorical phrase indicating the expressive quality of art, and implying that the elements of art, such as line, form, light and dark, color, and texture, when arranged according to aesthetic principles, produce a structure, pattern, or composition that may be interpreted or read as a language of expression. Whitford and Winslow in *Dictionary of Education.*

**lapidary.** A supplement to a bestiary (q.v.) describing the miraculous qualities of different species of stones. See JEWELRY.

**lapis lazuli.** One of the semi-precious stones, this has served as a material for carving and also as the mineral from which genuine or true ultramarine blue, the painter's pigment, is derived. That comes directly from pulverized lapis lazuli and is made somewhat more intense in color by a treatment which separates out the more highly colored particles from those which are colorless or have a contrasting color. —G.L.S.

**lappet weaving.** A process of decorating plain woven or gauze fabrics with embroidery-like motifs simultaneously with the weaving of the ground. The pattern is formed by an extra warp thread, heavier than the ground. See weaving. —G.W.R.

lat. See INDIAN ART.

**LATE ANTIQUE ART.** (NOTE: The present article on Late Antique art will be limited to a consideration of the last monuments of pagan art to be made in the Roman empire. Although Early Christian art, q.v.) in both its eastern and western manifestations is a part of Late Antique art, this development is omitted here for reasons of clarity and brevity.)

*Introduction.* By the Late Antique period is meant chiefly the twilight of the classical era, the final chapters of Roman imperial art, particularly in those many remote provincial centers within the artistic web that Rome spun over the world. Late Antique art, esp. in its regional manifestations, represents a phase of artistic expression interesting not only for its intrinsic aesthetic merit which, contrary to popular opinion, is sometimes considerable, but also for its revelation of a period of culture when the old classic humanistic values were locked in a death struggle with the dynamic and overwhelming forces of Oriental and barbarian art, a struggle that was to end with the victorious emergence of mighty and new spiritual forces that produced mediaeval art in the West and the great and truly ghostly beauty of developed Buddhist art in India and the Far East. Classic art, which held a mirror to catch the familiar friendly face of nature, was basically

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

no more compatible with Oriental art and its endless yearnings after the other world than it was with the fantastic and dynamic imaginings of the barbarian soul in Gaul and Britain. In Late Antique art we have the spectacle of artists completely reshaping the material terms and techniques of classical art that were fundamentally unsuited to expressing the spiritual ideals of non-materialistic beliefs. Herein lie the reasons why classical art could not survive in a world whose thoughts were beyond Nature and the accidental beauty of the human form. And it is precisely as an exemplar of this universal process involving the death of classicism and the rebirth of spiritual expression in art that the production of the Late Antique period is of such particularly vital import.

The changes that took place in Late Roman art are sometimes attributed to a falling-off in technical ability co-incident with the gradual disappearance of schools and training centers for artists in the period of confusion that accompanied the disintegration of the Empire. Although this is partly true, it is also undeniable that many of the distortions and departures from the naturalistic norm of earlier centuries were deliberate and influenced to some degree by the ideals and techniques of Oriental art as represented by the artistic traditions of the peoples in the eastern Roman provinces.

There are a certain number of formal and symbolic tendencies distinctive of Late Antique works of art as a whole which, as is to be expected, may be seen developing in earlier monuments of Roman art. So, for example, the heraldic symmetry, notable in the strict balance of equal numbers of figures on the arch of Constantine of 315 A.D., may be discerned in works as early as the Ara Pacis of 9 A.D. The method of continuous narration in which successive episodes are presented within the confines of the same frame was of course developed in the spiral reliefs of the triumphal columns of Trajan (98-117 A.D.) and Marcus Aurelius (161-180 A.D.). So, too, the universal tendency to frontality may likewise be discovered in certain reliefs from the monuments of Trajan, such as the arch of Benevento. Again, the principle of hierarchic scaling has its beginnings in the column of Trajan in which the figure of the Emperor is enlarged to emphasize his importance. The Late Antique device of inverted perspective might be pointed out in monuments as early as the 2nd cent. A.D. The general disproportion in the scale of the figures and their setting, so pronounced in the reliefs of the Constantinian period, is already a fully developed formula in the purely symbolical architecture of the reliefs on the column of Trajan. The lack of proportion in the human body, marked by an expressive rather than a normal enlargement of the head, may be already seen in the 3rd cent. reliefs of the arch of Septimius Severus (193-211). In exactly the same way the total disintegration of a unified spatial conception may be seen again in the Trajanic reliefs in which the suggestion of spatial existence is symbolical rather than optical. At the same time the disappearance of the unity of time and place in Late Antique reliefs is to be noted in monuments of the 1st cent. A.D., in which actions taking place at different times are arbitrarily shuffled together in the same composition. The violent contrasts of light and dark, which completely displace the earlier illusionistic style of relief of such monuments as the arch of Titus (79 A.D.), make their appearance as early as the Hadrianic period (117-138 A.D.) and in the impressionistic treatment of certain heads in the column of Marcus Aurelius. The trend toward the colossal, typical of 4th cent. portraiture, had its beginnings in the statues of earlier emperors represented slightly larger than life-size. Again, the employment of symbolical attributes in Late Roman portraiture is simply an outgrowth of such earlier types like, for example, the Prima Porta statue of Augustus (27 B.C.-94 A.D.) representing the Emperor in military gear, emblematic of his power as *Pacificatur Mundi*.

The gradual breaking down of the Hellenistic tradition was already under way in the far-flung provinces of the Empire as early as the 1st and 2nd cents. A. D. There the local Oriental or barbarian traditions hastened the disintegration of the humanistic classical ideal. It is customary to classify under the Late Antique period the art of Byzantium from the founding of the new Rome by Constantine until the emergence of truly Byzantine art under Justinian.

It seems that whatever creative impulse was left in the 3rd and 4th cents. flourished not so much in Rome the city, but along the axis of the Empire from Britain to the Parthian border: more and more strongly the forces that were to culminate in the medieval ideal came from the circumference of the Roman orbit; by 300 A.D. the creative power at the center had died. In these

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

later centuries we should think in terms of Roman imperial art—the art of the Empire—rather than Roman art. This will account for the uniform character of all Roman provincial art and the sometimes baffling synthetic character of its later development.

The principal monuments of Late Antique art, such as the arch of Constantine in Rome and the later Imperial portraits, are conceived in a form language completely distinct from the standards of earlier centuries. Classic forms come to be disintegrated, and the conception is now in a linear, frontal style that seems almost like a return to the archaic. The figures in relief become isolated and take on an inhuman rigor. A luminous spiritual quality animates the mask-like faces with their enormous eyes. The drapery is reduced to a kind of mesh of ornamental striations. These are all devices intended to emphasize the spiritual rather than the material nature of humanity, the ghostly inner self rather than the outward physical body.

An analysis of a few monuments selected from the principal centers of artistic production in the 3rd to the 6th cents. A.D. will suffice to reveal the essential character of Late Antique art in general.

*Rome.* In Rome itself those sections of the arch of Constantine which were actually carved in the 4th cent. are typical of this last phase of classical art. In the reliefs of Constantine's triumph over Maxentius the figures arranged in bands with a strict adherence to the principle of isocephaly appear as isolated units in a poster-like flat pattern of light and shade. They are arranged in a completely frontal and hieratic fashion, and appear as symbolic rather than descriptive portrayals of the human form. There is no projection forward or back, and what movement there is is completely lateral. The principle of hierarchic scaling makes its appearance in the slight enlargement of the figure of the Emperor which is also somewhat raised above the crowd to signalize his eminence.

A style of portraiture of a spiritual effectiveness such as the world had never seen before is to be found in the likenesses of the emperor Constantine and his successors. We find a new and abstract system of construction in which all signs of physical life in the face are subordinated to the radiation of a ghostly presence. The sense of human strain already characteristic of certain earlier Roman portraits is transmuted into a kind of ecstasy. The eyes begin to gaze upward out of the world with a blazing fervor; so—Constantine's chronicler Eusebius tell us—the Emperor was invariably portrayed in prayer with his gaze straining heavenward. The eyes become the chief unit in what is no longer a real physical personage but a soul aspiring towards its god. All the other features are no more than a decorative enframement of the spiritual power of the eyes. Here we have no ephemeral, momentary likeness, but that constant structure lying behind the incidentals of phenomenal appearance. The Late Antique period is marked by a re-appearance of the colossal statue, no longer for the representations of the Olympian god but for the specific designation of the Emperor as the more than mortal Cosmokrator and stupendous symbol of Empire.

ARCHITECTURE. The tendencies toward the dissolution of classical form, illustrated by the sculpture of the Late Antique period in Rome, are no less apparent in the architecture of the period. So, for example, the carving of the Corinthian capital, as seen especially in the buildings of Baalbek, Palmyra, and Palestine, could be taken as an index of the reduction of organic form and structure to a shimmering, immaterial pattern of staccato light and dark. In exactly the same way the façades of Late Antique buildings, notably the triumphal arches, become a sharply defined web of chiaroscuro in which all structural solidity is dissolved. One would have to consider, too, the culmination of the treatment of the orders in the arcades of Diocletian's palace at Spalato, in which the Roman arch is wedded directly to the Greek column. The arcade itself is a new spatial device peculiar to the Late Antique period. The palace complex itself is a symbol of the isolation and separate existence of the divine soverign. It is not surprising that following the new spiritualizing tendencies the dome, immemorial emblem of the sky in eastern architecture, comes more and more into prominence in the buildings of the Constantinian period that prophesy the triumph of domical construction in the symbolical architecture of Byzantium.

PAINTING. The painting of the Late Antique period is marked by exactly the same changes in the conception of form and space demonstrated by the sculpture of these centuries. This transformation, already discernible in Late Roman wall-paintings, may be admirably illustrated by the illuminations of the famous Vatican Vergil. All suggestion of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

material space has disappeared. The landscape is arranged in a series of zones or flat bands behind the prominent figures in the foreground. An exotic impressionism in color seems to parallel the treatment of sculpture as a design in chiaroscuro. Other features of Late Antique painting will be discussed at greater length in the section devoted to art in the Near East.

*Byzantium.* Constantinople, the new Rome founded by Constantine on the Golden Horn, was perhaps even more than the capital of the western Empire one of the last citadels of Hellenism. Some of the most famous statues of classical antiquity ornamented the squares and porticoes of the city until they were destroyed by the Venetians in 1204. The study of pagan Greek literature had never completely died out. It is for these reasons perhaps that so many monuments of the 4th and 5th cents. in Byzantium retain a distinctly Hellenic flavor. So, for example, the relief of a Nike from the Golden Gate, now in the Ottoman Museum, might at first be mistaken for a monument of the 5th cent. B.C. A closer inspection will reveal, however, that the body is hardly conceived as a physically articulated organism, and that the drapery, far from revealing either its own or the body's structure, is a reduction to a completely linear pattern of the Phidian scheme of drapery.

One of the most typical examples of Late Antique art in Constantinople is the base of the obelisk of Theodosius, erected in the Hippodrome in 405 A.D. Many of the techniques and concepts noted in the arch of Constantine are here brought to their final development. Figures are completely frontal in their rigid alignment. In a sort of combination of the principles of inverse perspective and hierarchic scaling, the figures performing below, in front of the royal box, are represented in a much smaller scale than the effigies of the Emperor and his courtiers. The only truly realistic figures are those of the kneeling Gothic barbarians. Extremely moving heads with their straining intensity of expression reveal a type of naturalism stressing pathos and suffering that is found in many examples of Roman provincial art in Europe.

*Provincial art.* It has been suggested that during the 3rd and 4th cents. A.D. the real centers of vitality in Roman art were in the provinces of the Empire where the gradual rise to dominance of Oriental and barbarian tendencies led to just those stylistic changes in Roman sculpture that have been noted in such monuments as the arch of Constantine. The human element in the art of Rome provided an acceptable and often vigorous means of expression. The change from classicism in Roman provincial art to a kind of dynamic expressionism was a turning from a cold and exhausted idealistic art to an art expressive of religious and ethnic ideas. The progressive disintegration of the classic ideal in the provinces was quickened by the existence of religious and racial groups that conceived their deities in abstract rather than representational, symbolic rather than concrete, terms. The best of the provincial Roman sculpture—from Gaul, Germany, and Bulgaria, to name a few centers—represents a purposeful transformation of the classical style into very much the same abstract and expressionistic formulae that distinguish western religious art at its moment of greatest tension in the Romanesque period. The notable triumphs of ethnic portraiture, seen, for example, in the reliefs of the Neumagen grave monument, seem marked by that suggestion of an inner radiance and spiritual intensity that distinguishes the sculpture of the Gothic age.

*The Near East.* The art of the Roman province of Syria comprises the remains from Antioch on the Orontes, the garrison town of Dura Europos, as well as many examples of sarcophagi generally classified under the designation Sidamara, from the site where most of the important examples have been found. The monuments of Palmyra and Nabataea represent an even more Orientalized type of Hellenism.

The principal remains from Antioch consist mainly of the pavement mosaics that decorated the patrician villas of this famous capital. Many of these decorations may be classified as Late Antique in their revelation of the gradual breakdown of the illusionistic technique, seen in the Pompeiian figure-painting of the third and fourth styles. Both subtlety of modelling and suggestions of light and atmosphere have disappeared, and the figures are now harshly modelled by shading that is little more than a thickening of the outlines. The forms have a strangely rigid and hieratic quality; in the nudes the muscular structure is more of a pattern than a definition of anatomy.

The city of Dura Europos on the Euphrates was essentially a military post that changed hands on a number of occasions from the Romans to the Parithians. Its art presents just that intermarriage of occidental and oriental techniques that is so distinctive of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

all Late Antique art. The most notable example of painting at Dura was a long painted frieze in the temple of Bel. The priests of Bel, like frozen effigies fixing the spectator with their great hypnotic eyes, are isolated against the background essentially flat and without depth, as though by this elimination of all suggestion of actuality it was intended to project the principal figures—the priests as symbols of perpetual sacrifice—the more forcefully and with the minimum of distraction. In this work of the 1st cent. A.D. hierarchical rather than optical criteria are dominant. Attributes and ritual gestures have completely replaced action and drama. Among the other pictorial remains in Dura include the decorations of the synagogue arranged in hieratic zones on the walls of the sanctuary. These were presumably completed about 250 A.D. Hieratic frontality, disproportion of figures and architecture, the conception of the forms in flat linear terms are among the many elements specific to Late Antique art. Both paintings and sculptures dedicated to the cult of Mithra have been among the principal finds at Dura Europos. It seems reasonable to suppose that the diffusion of the cult of Mithra, the divine toreador, to every province of the Roman empire was one of the most potent factors in the interweaving, not only of the Oriental mystery religious, but also of Oriental concepts and forms in art, into the whole fabric of the Roman empire.

The principal examples of the Asiatic sarcophagi are now gathered together in the Ottoman Museum in Constantinople. Although there has been some dispute as to their origin, it is now generally conceded that the chief center for the manufacture of these sepulchres was Sidamara in Asia Minor. Their decoration generally consists of figures of gods and goddesses centered in the niches of an arcade that enframes the sarcophagus. The resultant isolation of the forms is one of the chief traits of Late Antique art. The so-called *homme-arcade* motif was to find its way into Early Christian in the West, and is frequently found as a decoration on the Buddhist monuments of Afghanistan and northwestern India. Although many of the figures on Sidamara coffins reproduce heroic classical types, the forms have a sharpness and hardness in modelling and are conceived more as effective silhouettes than as plastically conceived masses. Not only the figural sculpture but also the lace-like decorative patterns clearly suggest the *Tiefendunkel* that comes to be distinctive of 4th cent. sculpture in Rome.

The art of Palmyra consists mainly of the innumerable grave portraits carved from the 1st cent. A.D. until the destruction of the desert metropolis by Aurelian in 273 A.D. Here again is a method of direct formalized expression with the elimination of all suggestion of physical realism. The body is reduced to a linear pattern of lines and simple abstract surfaces of planes. Absolutely rigid frontality prevails in all these grave portraits, and the eyes are given an enormous ghostly prominence. The minute treatment of the drapery patterns and jewelry in many of the Palmyrene portraits is to be interpreted not as realism but as a symbolic attribute of the rank and wealth of the deceased. These sculptures from Palmyra and the highly similar grave monuments from Nabataea are the most striking examples of the dematerialization of solid sculptural forms with the express intention of emphasizing the spiritual rather than the material nature of humanity.

*Egypt.* The grave portraits from the Fayum in Egypt, dating from the 2nd cent. A.D. and later, although made as pictures of individuals, are definitely abstractions: they reveal a reduction of the illusionistic and seemingly real light and shade of Roman and Pompeiian painting to an abstract formula of flat planes and thick contours—a simplification that immediately detracts from the reality of the form. The eyes too come to be enormously enlarged as if the better to suggest the indwelling ghostly presence of the dead. One could rightly say that they are "soulful" because, like the Palmyrene grave reliefs, these are portraits of the *spirit* of the deceased rather than replicas of his physical self.

Although the discussion of Christian art is omitted from this article, it is to be noted that the art of the Coptic Church in Egypt during the first six centuries of the Christian era must be regarded as a phase of Late Antique art. Subjects and techniques of pagan and Egyptian mythology survive, but these, as well as the Christian subjects, are handled in a manner distinctive of this local school. It happens that textiles are the principal survivals of Coptic culture, and even the sculpture is reduced to a patternized formula dryly and deeply cut, that is distinctly suggestive of a flat black and white design in weaving.

*The Orient.* Continuing our investigation of Late Antique art in the East, we find that in many respects the art of Sasanian

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Persia (226-632) presents the same mixture of classical and Oriental elements that is at the root of this whole world-wide manifestation. In this case the oriental elements are revivals of themes and techniques of the Achaemenid period; these are combined in rather haphazard fashion with Roman motifs and methods. Recent excavations at Shapur have revealed that Roman craftsmen were employed by the King of Kings, following his defeat of the Roman emperor Valerian in 260 A.D. The famous relief at Naqsh-i-Rustam, memorializing this victory, has the rigid symmetry and frozen, static quality of Achaemenid art, combined with such devices as over-lapping planes of relief and other details of Roman origin. The famous Victories or angels decorating the grotto of Khosrau II (590-628) at Taq-i-Bustan are the exact Sasanian counterparts of the Nike of the Golden Gate of Constantinople.

It was largely due to the intimate commercial relations between northwestern India and the Roman Orient that a local school of Late Antique art came into being in the province of Gandhāra in about the 2nd cent. A.D. Although a survival of Hellenistic culture in these regions during the centuries after the invasion of Alexander of Macedon may have had something to do with the origins of this school, both the types and techniques of Gandhāra sculpture are so closely related to Late Roman art and to the work at Palmyra there can be little doubt that the so-called Greco-Buddhist school of art is simply the easternmost extension of the Late Antique styles. (See INDIAN ART.)

*Conclusion.* It must not be supposed that the development seen in Late Antique art came to a sudden and abrupt end with the final collapse of the Roman empire. The tendencies initiated in the twilight of the Roman world really attain their final expression in the art of the Byzantine empire. It could even be said that certain aspects of Romanesque and Gothic sculpture are the final steps in what might be described as the spiritualization of Graeco-Roman art. In exactly similar fashion the local schools of Late Antique art in India and Iran exercised a powerful influence on the entire later development of religious art in Central Asia and the Far East. In many respects Late Antique art belongs to the culture of the Middle Ages. It could be said to represent the same metaphysical reinterpretation of classical form as the doctrines of Plotinus in relation to the thought of the Greek world.

**La Tène art.** See Celtic art.

**lateral parts.** See STAGESETTING.

**LATIN AMERICAN ART.** Twenty independent countries, from Mexico in the North to Chile and Argentina in the South, occupying more than half a hemisphere, extending from the temperate zone across the tropics to the temperate zone again, with great variety of climate and topography, and varying national and racial heritages and mixtures, necessarily present a diversified historical art development and considerable variety in contemporary art.

Historically this area of the Western Hemisphere formed the Portugese Colony which is now Brazil, and, at the greatest extension of the Spanish power, the 8 Spanish colonies known as Vice-royalties and Captaincies General, administratively distinct, and also distinct in cultural development and in character. These original divisions, based in part on the order of Conquest and in part on pre-Conquest native circles of influence, furnished the frame of development of art during Colonial times, and to an extent determine certain art tendencies even today.

All 20 countries use Spanish as their official language, with two exceptions: Brazil, where Portugese is spoken, and Haiti, French since 1697, where French is the established language.

*Colonial period (16th to 19th cent.).* The Spanish-speaking countries—all colonies of Spain before the 19th cent. wars for independence,—derived their principal influences in all the arts through and from Spain. Soon after the Conquest (Mexico, 1521; Peru, and Ecuador, 1534), plans for towns and buildings, and in some cases architects, painters

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

and sculptors, arrived in the principal centers to fill the need for construction of settlements, administrative buildings, and the churches that were the first permanent structures after military conquest.

In the great early centers of the Spanish Colonial Empire, where Colonial art in all its forms developed and flourished most richly during three centuries (the Vice-royalties of Mexico, Peru and New Granada and the Captaincy General of Guatemala, corresponding approximately to what are today Mexico, Peru, Bolivia, Colombia, Ecuador and Central America) the Spaniards found well developed Indian civilizations. These were very different from Spain's European-Moorish Christian tradition, but they had achieved impressive tangible artistic expression. Their Indian creators had trained hands, skills in construction and decoration, that made them apt workmen in the imported style imposed by the Spanish conquerors.

The great numbers of buildings erected during the Colonial period reflected Spanish styles, with more or less local adaptation and detail. The earliest structures rose on the West Indian islands, first stronghold of the Spanish power, where, in Santa Domingo, Porto Rico and Cuba, fortresses, churches and fortified dwellings date from the early 16th cent. and are little more than direct importations of utilitarian forms. The original and vital Spanish American architecture, derived from Spain but with character of its own, and all the arts that accompanied it, took form slightly later in the continental colonies that coincided with the regions of high pre-Conquest civilization. (See Mexican Colonial Architecture; Spanish Architecture in the New World.)

Sources of buildings, and even more of decoration and other art work, were varied. Among the missionary builders of churches were men who knew a little of architecture, painting, and sculpture, when professionals were lacking, as they frequently were outside of the principal settlements. They planned the adornment of their churches inside and out. Spanish, Italian and Flemish art works were imported, and sometimes ornaments as well as buildings were fashioned after remembered Spanish originals. Illustrated books were fertile sources, and engravings of European architecture, painting and the other arts served as models and suggestion for paintings and sculpture and ornament as well as for architecture and detail in the New World in places and cases where the connection with Spanish arts was not more direct. As always in Colonial societies great effort was made to establish in the new setting all that had been the customary adjuncts of civilized life at home, as quickly as it was possible to do so. Here it was not only a need of the settlers, but as well a device for subduing the Indians and establishing a pattern of life and of belief for them.

Side by side with the importation and imposition of Spanish patterns of living and of art styles, which in many instances absorbed some aboriginal elements or influences, or took on adaptations to new conditions, there continued intact native arts and crafts, notably those for every day use. They profited in some cases by improved techniques and added resources acquired from the Spaniards, but continued essentially unchanged otherwise, and apart, even as many habits of living did. Many of the arts and crafts existing today among the people in countries where large Indian populations persist undoubtedly exemplify such a history of continuous practice, side by side with those imported, just as details of local customs and living intermingle the influences that are so difficult to disentangle of the double inheritance of the aboriginal and of the superimposed Spanish civilizations.

By the end of the 16th cent. a considerable number of European artists were in Mexico and in the other older colonies. At the same time native artists and artist-craftsmen, of Spanish, of Indian and of mixed Spanish and Indian descent, but trained entirely in Spanish styles and traditions, began to appear, and from that time on took a dominant part in the development of Spanish Colonial art. Some few went to Europe for training and returned. Most learned from imported European art or from the immigrant European masters, working out in some cases a style reflecting faithfully their originals and sources, in others making a considerable departure to form a personal style or to conform to a local group style.

All the principal colonial capitals had by the late 16th or early 17th cent. groups of painters and sculptors of some interest. In Mexico, the diverse influences of the Renaissance were firmly established by 1600. A little later local centers with local styles were to develop, and native-born artists with distinctive personalities became numerous, not only in Mexico City, but in other cities throughout the Vice-royalty. In general, Mexico's colonial painting carried on faith-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

fully the Renaissance tradition and reflected Spanish styles and tastes, with some time lag to be sure. Folk and popular and provincial artists did not conform, of course, but the main current of competent professional Mexican painting found culmination in a baroque decorative and monumental style of originality and considerable grandeur and power in the late 17th and early 18th cents.

In the other colonies, the same influences were active and much the same course of development occurred. In the 17th cent. each capital or cultural center had its Colonial master, thoroughly trained in European tradition, familiar with European styles of his time, working brilliantly in accord with them, but competent in his own right and making his own contribution, to stand as the Old Master of national art history.

The complete roster of those painters counted important in the four Colonies which contributed most to art development from the late 16th cent. to the 19th is too long, but the significant achievements can be summarized in a few recognized leaders of each place and time, of whom something is known. and to whom extant works of some importance are attributed, viz.: *for Mexico*: Baltasar de Echave Orio (Sp. c. 1548-Mex. c. 1620); Baltasar de Echave Ibia (c. 1583-c. 1650), son of preceding; Baltasar de Echave Rioja (1632-1682), grandson of Echave Orio; Cristóbal de Villalpando (c. 1639-1714); Miguel Cabrera (1695-1768); Fray Miguel de Herrera (act. 1725-1752); José de Ibarra (1688-1756); José de Paez (c. 1715-after 1790); *for Guatemala*: Francisco (de) Villalpando (17th cent.); Antonio de Montúfar (17th cent.); Thomas de Merlo (late 17th cent.-1739); *for Columbia*: Gregorio Vásquez de Arce y Ceballos (1638-1711); *for Ecuador*: Miguel de Santigo (c. 1605-1673); Nicolas Javier de Goríbar (act. c. 1656-1688); *for Peru*: Francisco Bejarano (act. early 17th cent., Lima); Pedro de Saldaña (late 16th cent., Cuzco); Lorenzo Sánchez, Juan Osorio, Marcos Zapata and Juan Espinoza de los Monteros (all active in the 17th cent., Cuzco).

Naturally, most painting, esp. of the earliest period, was religious in subject. A certain amount of portraiture was done from the beginning, and became relatively more important in the 18th and early 19th cent.

In some places and at some periods, the imported styles, were weakened by lack of direct contact, or diluted or modified by divergent personal interpretations, local influences, in part indigenous, or by local taste, to take on the character of a distinctive style, derived from the common tradition but changed profoundly. Cuzco is the clearest example. It developed its own recognizable series of styles, in part production of workshops or anonymous artists but with some leaders known by name. Quito, Lima, some of the provincial cities of Mexico in the 17th and 18th cents. had groups practicing distinctive styles with regional provincial characteristics of great interest.

In some cases it was a special product as well as a style which made a center famous. Most centers probably produced for local consumption, but in a few cases their specialties became famous and they exported. Thus Quito, which attained enough celebrity in painting to send works as far as Chile, developed in addition a specialty of fine polychrome religious sculpture. Spanish sculptors brought knowledge of the art to Quito, but the long line of gifted Colonial sculptors invented new types and refined the technique. Among many, Father Carlos of the 17th cent. and the Indian Caspicara of the 18th are perhaps the most important. Tradition has it that in the 18th cent. Quito exported its figures to every part of the Spanish-speaking world.

Guatemala likewise became famous for polychrome sculpture which was sought throughout Mexico and Central America. Among a number of sculptors famous in the 17th cent. and known by name and by attributed works Alonso de la Paz (1605-1676) is the recognized great master. Quirio Cataño, active in the last half of the 16th cent. was scarcely less celebrated, and Evaristo Zúáiga whose important work dates from the early 18th cent. carried on the tradition.

Polychrome sculpture, to adorn altars and decorate chapels and churches, was produced widely, and ranged in quality from the delicate perfection and richness of Quito and Guatemala to crude, late folk art figurines —still most frequently of saints,—but heartily popular and rudely provincial, produced at a distance from the sophisticated centers.

Sculpture in both stone and wood was highly developed in the Colonies of Mexico, New Granada, Guatemala and Peru. Stone sculpture had ample scope as decoration surrounding doorways and on the façades of churches, and ranged from the elaborate and rich detail of cathedrals and important churches in such leading centers as Mexico,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Puebla, Lima, Cuzco, Quito, La Paz to a few moldings or symbolic motifs for the simple chapels and churches of monastic establishments and of small cities and villages everywhere. Some was used on public buildings and on the more pretentious private dwellings as well, usually above doorways. Sometimes pulpit or font was carved stone, or a fountain or a free-standing cross in a churchyard had carved ornament. Spanish styles were influential, but very often in detail they were modified or enriched by local influences, sometimes clearly indigenous, or by personal fantasy, or perhaps improvisation taking the place of academic knowledge.

The richly ornamented altar, reredos, chapels, doors, choir loft, pulpit, choir stalls, and other furniture of church and sacristy, and the furnishings of public buildings and homes, offered opportunities for wood carvers. Usually these artist-craftsmen in wood, as in stone, were anonymous. Though the general quality of their work is fine, with abundance of skill and imagination and a sure sense of decoration, only by exception was it thought of as creative art in the same sense as paintings and the polychrome sculptures were. In the majority of cases the carvers were probably of Indian or part Indian descent. Skilled gilders and painters usually completed the work of the carvers, and in a few cases also gained such fame as to be known by name. In Peruvian, Bolivian, Ecuadorian and Colombia churches, the original rich interior decoration, including the carved and gilded altars, with their paintings and polychrome saints, are usually preserved. Mexican churches have in most cases lost their altars and chapels, and with them something of the richness characteristic of the best of the Latin-American decorative styles.

In Mexico, Ecuador and Peru the abundance of silver fostered fine work, in church ornaments and domestic ornaments and tableware of great weight and richness, baroque in style. Fine work in iron and bronze was done also, in window grills, door grills and studding, on locks and hinges and other hardware for house and furniture.

Art has no such long nor rich history in the other four Colonies (the Captaincy General of Cuba, the Captaincy General of Venezuela, the Vice-royalty of Buenos Aires, and the Captaincy General of Chile). These regions were remote from the great centers of Mexico and Peru, could not draw on established Indian civilizations with their ready prepared skills, and, in the case of Buenos Aires and Chile, settlement came later and material growth was slower.

Venezuela, notwithstanding its proximity to Columbia and the Caribbean, has little to show before the end of the seventeenth century, perhaps partly because of losses in the disastrous earthquake of 1641. In the eighteenth century, it had stone and wood carvers of competence who decorated churches and houses, and skilled cabinet-makers who turned out fine furniture and woodwork. There were painters and religious sculptors from the seventeenth century on, but they are not to be compared in number and achievement with those of the more active Colonial schools.

Cuba began immediately after the discovery of America its growth in architecture, but in painting nothing remains earlier than the work of José Nicolas de la Escalera (c. 1734 c.-1804), a painter of religious subjects in the accepted European style of the time.

Northern Argentina, in close contact with Upper Peru, shared its artistic development to an extent, and churches in Córdoba illustrate admirable achievement in stone carving and woodwork by the late 17th and early 18th cents., and in the old houses of Salta, fine 18th cent. metal work, wood carving and stone work are proof of the skill of the local artist-craftsmen. The Colonial churches of the region, founded by missionaries, recall their stately and rich prototypes in Peru, in some cases, but with less sophisticated style, and a sincerity and directness and, frequently, indigenous influences as well, that give them a special savor.

In Buenos Aires and elsewhere in Argentina, architecture, and in general the accompanying arts, date in their oldest examples from the late 18th cent. However, in addition to the late art development under Peruvian influence in the North, the Vice-royalty of Buenos Aires (which included, in addition to Bolivia and Argentina, what is now Uruguay) offered one native art development:—that fostered by the Jesuit missionaries in the 17th and first half of the 18th cent. among the Guarani Indians. This was in territory which today is divided between Argentina, Paraguay and Brazil. Now known only by ruins and a few pieces of sculpture which have found their way to museums, the Guarani towns of brick and adobe, and the churches of stone, roofed in wood, represented an individual development of great interest, dependent on the skill of the Indian converts under the able and energetic direction of the Jesuits. In addition to elaborate decoration

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

on the façades of the churches, in which the detail appears almost always to be indigenous, religious figurines of saints in polychromed wood were produced for church decoration, for the local need, but also for export as far as Buenos Aires. Both carvers and decorative painters—trained Indian craftsmen,—are supposed to have worked in Buenos Aires and elsewhere when needed. The Guarani artists included painters of religious pictures, and engravers, but only scattered examples of their work are known, and it appears to have been decorative rather than strongly creative.

Architecture and art developed relatively late in Chile. A severe earthquake in 1647 destroyed earlier buildings and with them work of native craftsmen in altars and other church ornament. By the late 17th cent. much art had been imported from other centers in South America, some native sculptors had appeared, painters from Cuzco had made some contribution to the development of local painting, and the baroque style also was having its influence. In the 18th cent. a group of European craftsmen was imported by the Jesuits and gave considerable encouragement to art of all kinds.

Brazil stands apart from the remainder of Latin America, for its vigorous Colonial art derives, like its language, from Portugal, not Spain. In its territory no great Indian civilization existed and the flowering of its architecture—an original development of Portuguese baroque—took place in the 18th cent. (See Brazil, Colonial Architecture of.) Franz Post, one of the six Dutch artists imported by Prince Maurice of Nassau during the 30 years of Dutch occupation in the 17th cent., was the first to introduce Brazil's tropical landscape to European art. Neither he nor his companions left any trace on the art of Brazil, however. Church painting followed European styles, with something of the same exuberance of the architecture. The work that stands out in the Colonial period is the elaborate and sometimes somewhat bizarre sculpture of the celebrated and romantic cripple, called "Aleijadinho", who is associated principally with the statuary in Minas Geraes. His figures in both stone and wood never fail in power and expressiveness, and though their origins in Portuguese art are clear, they represent a personal and native development.

*The Nineteenth Century* in all Latin American countries was politically a period of unrest and revolution, marked by the continuous struggle, with greater or less difficulty, through battle and a varied series of political transitions, from the status of colonies of Spain or Portugal to independent republics. In the 18th cent. religious art had been less important; portraits, painted from the beginning of important personnages of the colonies, became increasingly numerous. In the 19th cent. portraits of the heroes of the revolution, and some historical academic painting—usually on a large scale—came into prominence. Except for portraits by self-taught artists, successful because of the intense desire for realism and expression, and the sincerity of the conscientious painters, European influences, largely French, but also Italian, were dominant. In the early years of the century foreign artists visited most of the countries, recorded charmingly their picturesque life, and sometimes stayed to become masters of drawing and painting. In 1828 an Academy of Arts was formed in Brazil and French teachers were installed. In most other countries, some comparable academic European direction was established by the middle of the century. Especially promising art students were sent to Europe for study, and invariably fell into academic styles. They returned, bringing the skills, but also the art ideas of Europe with them. There resulted everywhere, except among a few self-taught, naïve and dissident artists, whose work was relegated by their contemporaries to inferior rank if considered at all as art, a dominant, vigorous, transplanted European academism in both painting and sculpture, everywhere in Latin America.

For the most part, though these men did found the tradition of the craft of the arts in their respective countries, their work and their names have only historical interest. However, a few painters by their personal force either escaped occasionally from the academic stamp to produce some work of essential quality, or stood aside from the common tradition and yet made a direct contribution to art development, sometimes through rediscovery by artists of today. A few type examples are worth noting in this period: Franklin Rawson (1819-1871) for portraits, sensitive and occasionally naïvely decorative, and Prilidiano Pueyrredón (1823-1870) for portraits and genre scenes of quality and power, both of Argentina; Juan Manuel Blanes (1830-1901) for portraits, historical compositions of great size, and genre paintings of vigor, of Uruguay; Pancho Fierro (act. mid 19th cent.) lively recorder in watercolor and drawings of contemporary types and customs in a direct, personal, and

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

somewhat naïve style, of Peru, whose work is greatly savored by the Peruvian *indigenistas* and has had some little influence on contemporary painting there.

*Contemporary art.* In the 20th cent. gifted students continued to go from their respective Latin American countries to Europe to complete their art training. Paris was the most popular center for study, though a good number went to Spain and Italy, and a few to Germany. Most traveled also in Italy, some in Spain and a few in Germany, to study the art of the museums. By far the majority, wherever they went, followed the traditional course of academic art, and that was what they took back to their own countries, what prevailed also in the academies of art,—usually national schools supported by their respective governments,—and what was approved by cultivated taste among the public at home. Some few were deeply stirred by the currents of futurism in Italy, of cubism and other new movements of the period from 1910 on, in France and in Germany. Some few, like Diego Rivera (1886- ) of Mexico, Emilio Pettoruti (1892- ) of Argentina, entered directly into current movements, assimilated them and contributed to European styles for a short period, but for most the new tendencies were a stirring to self-examination, an encouragement to venture from the deep-traced paths of tradition, and a stimulus to seek their own way. At second hand, the impulse toward freedom affected even those who developed at home, as well as those abroad who did not directly enter into any of the new European movements. This stimulus from Europe, and the lifeless state into which academic art had come in its imported forms, together account for new developments in the art of all countries during the 20's and 30's.

In general, it can be said that there is everywhere a tendency to develop art in increasing independence from Europe, and with a growing reference to national environment and sources. Sometimes it is a deliberate effort to discover the new and exotic, to derive from native sources, and, sometimes, to depend on content alone to create a new art. More often it is a sensitive exploration of the environment, which may reflect its conditions and characteristics without any obvious recourse to subject matter. The results range all the way from Mexico's vigorous, original, independent school of painting, deeply rooted in the past and present of its people and country, to the gradual and subtle adaptation of international expression to the national scene in the contemporary art of such countries as Argentina and Chile.

Interestingly enough the two major tendencies exemplified respectively by Mexico and by Argentina, coincide to an extent with the presence or absence of the pre-Conquest Indian civilizations, so that it is no exaggeration to say that the pattern of the Indian past contributes to contemporary art just as it established the distribution of art development during the Colonial period.

Mexico's is the most brilliant example of a Latin American art development consciously turning to the sources of its own land and working out an independent movement. It has had numerous brilliant painters, and continues its development uninterrupted, and enriched by a vigorous evolution of styles in the work of successive generations of younger artists. (See MEXICAN PAINTING, CONTEMPORARY.) By virtue of its accomplishment it leads in this modern movement—that tendency to draw on indigenous material as subject and as source for contemporary art.

Developments similar to that of Mexico are to be seen elsewhere, but less powerful and less important. They appear logically enough as one of the accepted art expressions in most countries of strong Indian heritage, especially where the Indian past continues into the living present by virtue of large Indian or predominantly Indian populations. There is no doubt that the example of Mexico has had some influence both on the tendency in general, and on individual artists.

Peru is second only to Mexico in the development of its *indigenista* school of contemporary art. Its use of Indian subjects, as frequent though not exclusive material, gives it a superficial resemblance to Mexican painting, which disappears on closer examination. It draws its strength from simplified and rhythmic handling of themes of the country: Indian life, Indian villages, mountains, llamas, Colonial architecture, characteristic types and customs of the country. Its artists derive their patterns from the study of pre-Columbian Peruvian art, the Colonial period, and the Indian arts of today, with a tendency to stylize and abstract which results, in the work of some of the artists, in a type of expressionism, while others have developed a more purely decorative style. For the most part, there is avoidance of illustration, which is the danger of an art dependent on subject. No such impressive development has

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

taken place as in Mexico; neither in the dominating personalities nor in the number of active artists can Peru match Mexico. There is, however, the authentic savor of a sincere, workmanlike tradition deriving its themes and its expression from the country and its people, and feeling its differences from European art as a reflection of the differences from European environment.

Among the Peruvians should be noted: José Sabogal (1888- ), painter and teacher chief theorist and in many ways the leader of the group; Julia Codesido (1892- ), sensitive colorist and increasingly expressionistic painter; Camilo Blas (1903- ), working in bold color, often with humor, and with a tendency to stylize and to create linear patterns. A younger group continues exploring native themes and feeling, contributes personal styles of some interest, and promises to carry on development of a national art, freed from academic traditions, but sound in technique.

In other countries of Indian background and large contemporary Indian population there is also semblance of an *indigenista* movement in some form.

Bolivia has turned to indigenous material, and the most active contemporary tendency has been a decorative treatment of Indian types or typical scenery. For the most part, however, the indigenous interest has been illustrational—a discovery of picturesque and exotic subject matter by artists trained in Europe and essentially European in point of view. There has been no intimate understandnig and no real penetration in art into the land and its people. The dominant style has remained true to its academic origins, and has in no sense,—but content,—developed anything new, original nor really modern. A few younger Bolivian artists, both painters and sculptors, give evidence of having more to offer. Not all of them exploit indigenous themes, though all have a profound sense of the life of the Indian people and the ancient past of Bolivia in pre-Columbian and Colonial times. It is in their work that contemporary development of value is to be expected. Among a number should be noted Marina Nuñez del Prado, sculptor of Indian types and dances, in increasingly abstract rhythmic style; Roberto Berdecio and Antonio Sotomayor, painters of Indian types and scenes, occasionally. None of these artists is now resident in Bolivia.

In Ecuador, there are a number of young, gifted, powerful artists imbued with Indian life as it is a part of the present and past of the country, and using their studies of it and of the country as an avenue of emotional expression. They identify themselves with this Indian life and paint from within it as a well understood and valued heritage. Eduardo Kingman and Oswaldo Guayasamin (Calero) are promising examples chosen from a number. Beside them are Ecuadorians of well formed European training and tradition, some few academic and illustrational, most modern and sensitive, but not associated with advance guard movements. They paint either material that has no obvious connection in subject or feeling with the country, or when they paint native themes do so ably and well, but as outsiders. In this group Pedro León and Sergio Guarderas are examples. Finally there are some resident Europeans who find in the native themes occasion for stylizations, expressionistic distortions or decorations. Olga Anhalzer-Fisch and Jan Schreuder are typical.

The other country of large Indian population today, Guatemala, has no great art development. Its most eminent painter, Carlos Merida (1893- ), was originally associated with the Mexican movement, and at present tends toward abstraction, influenced in character, color and form certainly by his rich experience and feeling for Indian arts, but subtly, not obviously. Other painters in Guatemala, except for a minority who study Indian types in a purely illustrational if competent fashion, work entirely in an international modern style, sensitive and adequate and experimental, treating Indian and native themes incidentally.

Colombia, the remaining one of the regions coinciding with the great Colonial centers in which art and architecture flourished, and which before the Conquest had developed a high civilization, does not have a large Indian population today. It has artists of European training who use native subject matter as exotic illustration, a few younger artists, like Luis Albert Acuña, who know well the arts of the Indian past and from them have drawn stimulus for a personal style, and a large group of artists, for example, Ignacio Gomez Jaramillo, some of whom know Europe, especially Spain, who work in the Spanish and other European contemporary traditions with little regard for such native elements as persist still in their own environment. In comparison with the three foregoing countries these are scarcely perceptible in modern Colombia, for the Indian past is well overlaid

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

with European culture. The rise of an *indigenista* feeling is hardly to be expected therefore, and would indeed seem artificial except as it prompts a personal, lyrical and decorative expression in individual artists.

This is even truer of the other Latin American countries, which had no great Indian civilizations, and in which the Indian populations have either disappeared completely as in Uruguay, or have made no direct contribution to the cultural development of the country. It is not surprising to find the international patterns of modern art strongly established in all of them. A few of the leading countries have art movements and artists to note, with marked tendencies toward individual development within the European tradition.

Cuba has always felt close to both Paris and New York and reflects clearly the activity of both centers. Some of the School of Paris styles flourish there side by side with less advanced and more individual styles, but all derived predominently from French 20th cent. painting. Names of interest are Mario Carreño, Antonio Gattorno, Amelia Pelaez, Jorge Arche, Cundo Bermúdez.

Chile, following an extensive program of training its most promising artists in Europe in the late 20's, has developed a contemporary school in which Impressionism is dominant, with noticeable interest in the post-Impressionists Cezanne, Renoir and Van Gogh occurring, and a very few artists reflecting the School of Paris, and exhibiting a touch of surrealism and abstraction. Sculpture, well developed, has been influenced to good effect by Bourelle and Maillol. Representative tendencies are exemplified by Jorge Caballero, Hector Banderas, José Perotti, Camilo Mori, Armando Lira, Laura Rodig, Raul Vargas, Lily Garafulic.

Argentina shows more clearly the influence of the School of Paris, in the work of individuals and in the variety of styles. A few have come under the influence of Italian and Spanish modern movements, but French influence is dominant. Notable among the mature artists, European trained, who began by close association with European styles, later to evolve highly personal expressions of their own, are Horacio Butler (1897- ) and Emilio Pettoruti (1892- ). Butler, early interested in French modern movements, turned to scenes of hsi own land, deeply felt, strongly modelled, in well composed rather personal color harmonies. Pettoruti, who was associated with Italian futurism, continued a personal development of abstraction on his return to Argentina. Other names to note are Onofrio Pacenza, Lino Spilimbergo, Antonio Berni, Ernesto Scotti, Ramón Gómez Cornet, Alfredo Bigatti.

European influences are strong in Uruguay also. From the large group which reflects European styles in great variety, most interesting are perhaps the abstract painter J. Torres García and the original Pedro Figari (1861-1938) in his naïve, direct, clear-colored, sprightly memories of the Montevideo of his childhood.

Venezuela, like the other countries, sent its most promising artists to Europe for study. On their return these artists have carried on the traditions of contemporary Europe for the most part, though through Armando Lira, Chile's contemporary development has had some influence there, and a few of the younger artists have been interested in Mexico. Armando Reverón, Paris trained, but whose work has developed a highly personal style, is probably the outstanding personality among a large group of competent artists. Francisco Narvaez is an interesting sculptor.

In Brazil, too, the European modern art styles, and especially those of France, have had fertile influence. Despite a great development in functional modern architecture, which has made its own distinguished contribution to the movement, Rio de Janeiro inclines to be less progressive in the other arts than Sao Paulo, in which is centered the Salao de Maio and the whole focus of the more advanced art ferment of Brazil. European movements of the advance guard find adaptation and local exponents there in great variety. Candido Portinari is the only name as yet to be well known outside the country, but among others should be noted Lucy Citti Ferreira, Barbara Ruchti, Flavio de Carvalho, Manoel Martins.

The influence of European art is clear and has been dominant in these Latin American countries, and also in all those remaining which are not specifically mentioned here. This influence, however, has in most cases been a point of departure, and a fertile guide rather than a limitation. The artists of each country have worked freely within the congenial tradition, making their own personal contribution and adapting themselves and their work to their own environment. In general they have thought of themselves as belonging to an international movement, have thought of their respective countries as they

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

resemble Europe. Only as a minor trend, and not in the deliberate manner of Mexicans and Peruvians, have they usually thought of the art of their country as a nationalist expression, or of its possible national styles. In the last years of the 30's, however, there had been less movement to Europe, and with the attainment of maturity and assurance by those who had studied there earlier, a tendency to feel more independent artistically, more assured and self-sufficient, within the art growth of their own country, began to appear. This trend may foreshadow a growth of national styles in a more conscious way, as national local styles already are perceptible in fact. To be entirely self-sufficient in these countries of European art tradition seems scarcely possible, since, except for Argentina, there are no large collections to exemplify the tradition. There is likely to be, however, as a result of the war, a deepening of the consciousness of differences from Europe. This feeling may foster the development of national feeling and adaptation of European styles to a more consciously national expression.

In nearly all countries, even where there is no indication of any tendency toward national expression or feeling in painting or sculpture, there have been established within the last decade or two schools of applied arts, or movements among artist-craftsmen, which have deliberately, and with varying success, turned to historical national sources for design,—in pottery, ornament, textiles, etc. It is interesting to note also, that in the less formal arts of prints and illustration, well developed but scarcely regarded as art on the same level as painting and sculpture, there is much exploration of native material, even to the point of some influence on style, in countries appearing in their painting as predominantly European in tradition.

Countries which have produced notable contemporary work in prints are Argentina, where monotypes, etchings, and engravings achieve technical excellence; Uruguay, which also shows preference for metal plate prints; Peru and Ecuador, in both of which bold, decorative woodcuts, often on indigenous themes, are outstanding; Brazil, where some of the finest work by Portinari and Santa Rosa is in lithography, produces work in the other print mediums as well; and Mexico, which has established an active group of print-makers in all mediums, but finds the autographic lithograph and the decorative wood cut especially sympathetic.

*Mural painting.* In accordance with church tradition, mural painting was introduced early in the Spanish New World. Again in the countries of Indian civilization, Mexico and Peru, it was not a foreign idea, as Mayas, Aztecs and Peruvian peoples all had painted walls. Many of the early churches and monasteries were decorated with wall paintings, usually tempera on plaster, in color or in grisaille, with saints or with ornamentation, perhaps copied from books. The important development of murals in Latin American countries has been contemporary, however. Mexico led with the revival of true fresco in the early 20's under the leadership of Diego Rivera and José Clemente Orozco and others. This revival stimulated similar work in all other American countries, first perhaps in the United States, where both Orozco and Rivera executed important commissions in fresco, trained assistants, and by the topical and symbolic subject-matter designed for the instruction and indoctrination of the masses, showed the way to a large following who worked in fresco and other mediums with a like purpose. Their example had some influence everywhere in Latin American countries. José Sabogal of Peru has worked in fresco, but has not had an opportunity to do a large wall in his own country; Alfredo Guido of Argentina has done some murals and instructs in mural design; Candido Portinari has painted numerous murals, in fresco and in other mediums, both in Brazil and in the United States; Ignacio Gomez Jaramillo of Colombia has done a few frescoes in Bogotá. However, the only artist who has executed any considerable number of murals, designed, like those of the Mexicans, to teach a lesson and illustrate a theme, instead of serving a decorative purpose only, is the Colombian Pedro Nel Gomez, who has painted for public buildings in Medellín numerous monumental frescoes illustrating social problems and historical subjects of national life.

*Folk and Popular Arts.* The native crafts of the Indian peoples, as well as adaptions to their understanding of imported crafts and arts, all used as a part of everyday living, are the basis of folk and popular arts in the countries of Indian inheritance and population. Weaving of great variety and quality, and pottery of diversified forms and uses,—from pots to toys,—illustrate well such arts in Mexico, Guatemala, Ecuador, Peru and Bolivia, all notable centers of such production. Individual towns or localities often

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

have their specialties as, the pottery of Puebla, the lacquers of Michoacan, the textiles of the diverse villages of Guatemala or of Peru, the topos or shawl pins of Bolivian settlements. The wide range of Mexican popular arts and the variety of Guatemalan textiles are well known, for they have developed into an export and tourist trade as well as production for local use. The folk arts of the other countries are less known, for no tourist trade to speak of has developed. In Ecuador, baskets, textiles and carvings are the principal products. In Peru, besides weaving, elaborate knitting of dolls, caps and mittens is carried on, silver ornaments are made, wood carvings of llamas, and pottery depicting bulls are produced as toys. The most interesting craft is, however, undoubtedly the carving of gourds in lively scenes of musicians, markets and other episodes of everyday life, with great spirit and a sure sense of decoration.

In many countries of Indian culture, masks for dances given on religious festivals are an important craft. That is especially true of Mexico, Bolivia and Guatemala.

In the countries of European heritage some crafts, brought from Europe with the original settlers, or developments in response to special conditions, persist. Some forms of pottery and weaving in Chile and Argentina, the gaucho's silver studded belts and braided leather quirts in Argentina, are such examples, but they are rarer and less exotic than the crafts the Indian peoples preserve. In Brazil a certain amount of popular work is done by the Negroes in the Northern cities; —especially interesting are crudely but powerfully carved small figures that are probably fetishes much like those more aesthetically mature ones produced by their ancestors in Africa.

The ex-votos or miracle pictures produced in most countries on the occasion of cures, recoveries, or escape from accident or danger and put in churches as commemorative tablets,—naïve and childish often, but sincere and decorative work of some amateur or sign painter,—are among the most charming works of popular art. They are well known and valued in Mexican art, but they occurred everywhere, probably from very early times. Many were produced in the 19th cent. everywhere, and occasionally are still produced, just as the silver representation of legs or arms or hearts, ex-votos also, are still used everywhere as they have been for several hundred years.

The boldly carved and colored saints, often with homely attributes of daily and familiar life, and the processional images of provincial churches furnish other examples of folk arts.

In all countries, once the large cities are left behind, even including countries of European culture and good or comparatively good communications, like Argentina and Chile, individuals are still dependent on their own skills, and in more remote sections in less developed countries, like Bolivia and Peru and Ecuador, are largely self-dependent for all they use. The result is the making of many articles for their own use or for trade against other needed articles made by someone else. Usually these objects have some decoration or fineness of form that puts the best examples in the class of popular arts.

Few countries, at least as far as known, have the immense variety and richness of crafts that Mexico displays, but in the other Latin American countries there is undoubtedly much more to be discovered and explored in the field of traditional popular arts as well as of those of today, than has been as yet reported and described. See Academia Nac. de Bellas Artes, *Documentos de Arte Argentino,* 1940; Argentina Nat. Committee, *Fine Arts in Argentina,* 1939; Diaz, Victor Miguel, *Las Belias Artes en Guatemala,* 1934; Goodwin, Philip L. (Mus. of Mod. and on single artists. For helpful references and illustrations, usually periodical, see *Art* in annual *Handbook of Latin American Studies.*) —G.L.M.M.

**Latin American Music.** The music of South America is of Indian and Latin heritage. Analogous to the history of her countries, so in her music the Spanish and Portuguese elements are dominant, both interwoven into the features of an ageless native art. Yet, in addition to such a blend of musical idioms from the Old and New Worlds, there are other factors at work, ideological and technical, which are leaving a distinct imprint of modernism on contemporary music South of the Rio Grande. Thus modern Mexican scores, in spite of a certain affinity with the ancient forms and rhythms of the Indians, display a progressive attitude achieved from the study of the technically most advanced trends in European composition. Likewise, the truly representative works from Brazil, Argentina, Chile or Peru all show modern strides—from the advanced employment of the new electrogenic media of performance to that of the twelve-tone scheme.

Obviously, the geographical location of South America no longer involves artistic isolation. Today, radio and records flood music all over the vast continent with its wide prairies, thick jungles and high mountains. Formerly, it was but a small number of cosmopolitan musicians that had, in Latin America's big cities, real access to the new art from abroad. Now, with the turn of a switch the average South American may hear the music of Schoenberg, Shostakovitch, or of his progressive North American neighbors. It is clear that the contemporary style in Cuba, Guatemala, Colombia and the other Latin American countries could not remain unaltered with these revolutionary inventions of electrogenic rendition.

On the other hand, nationalization appears to be one of the outstanding trends in the music of many South American countries. Whatever its basis—nationalistic ideology or mere *l'art pour l'art* exploitation of the rich native folklore—there is a group of composers, esp. in Argentina and Brazil, who want to throw overboard any model imported from the old continent and want to retain as much as possible from their own tunes and forms.

Among the forms of specifically Latin American origin certain dance types are in the foreground. In fact, dances from South America are the very exportations which the rest of the world has eagerly accepted for more than one hundred years. Today, the Latin countries continue this tradition of vitalizing their own musical performances and those of the other continents with terpsichorean spirit. Several of the fiery and sentimental types, like the Brazilian Congo, the Cuban Habanera, the Argentine Tango, appear now in symphonic garb: their style has been transformed just as was the old Hispanic sarabande with its integration into the instrumental suite of the baroque.

Reviewing the composers from South America, the name of the Brazilian Antonio Carlos Gomes might be mentioned first—since his opera *Il Guarany* (using Amazon-Indian themes) had, as early as 1870, great international success and threw the spotlight on the musical production of his country. Today, the dominant position is held by Heitor Villa-Lobos, an extremely prolific musician of many activities and remarkable imagination. With the Brazilian Villa Lobos, the Mexican Carlos Chavez is today one of the best known Latin American musician. Dividing his activities between composing, conducting and teaching, he has placed organizations and men under his leadership in Mexico City into the *avant-garde* of interpretative progress. The Argentine composers José Maria Castro and Juan José Castro have gained reputation outside Buenos Aires. The latter is also musical director at the Teatro Colón, the most important South American opera house. In connection with Argentina the fact is noteworthy that Manuel de Falla, the greatest living Spanish composer, is now making his home there: this will doubtless cause further interaction between the musical idioms of the old and new Hispanic countries. —F.D.

**Latin American Literature.** See HISPANIC AMERICAN LITERATURE.

**lattice.** A decorative pattern of lines crossing each other at regular intervals to make regular openings of square or diamond shape.

**Latvia, art of.** Latvia, the central one of the Baltic Republics, was inhabited in prehistoric times by Finnic and Baltic populations and the early remains show the various types of East Baltic prohistory. They were abundantly adorned with swastikas of various forms in red and green areas.

Many of the antique decorations from the Iron Age still continue as popular adornments

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

and motifs and the folk art still maintains the purest native inspirations.

During the medieval period Christianity was introduced and most of the country fell under the control of the various archbishops and the Knights of the Sword. There were bloody battles between these groups but both represented Germanic influence and introduced into the country **Baltic Gothic** which is represented in Riga by such monuments as the Dome Church (originally started in Romanesque times early in the 13th cent.) and the St. Peter's Church with the highest wooden steeple in the world (commenced by 1416). Here belong also the House of the Black Heads started in 1330 but often remodelled.

Later during the Swedish and Polish occupations after the turning of the Teutonic Knights to Protestanism, the architecture shows the usual influences. With the coming of Russian domination in the time of Peter the Great, we begin to find the same types of architecture that were adopted in Russia. As a result, Riga represents the usual architectural features of the various centuries, with a great deal of restoration and reconstruction, while in the country districts there are also monuments of all periods.

In the field of painting, while there are some remains of medieval work, the various artists fell under Russian and German influences and it was not until the time of Adam Alksnis (1864-1897) that there begins a native Latvian school of painting. The artists of this group are particularly interested in landscapes and they show the same melancholy lyricism, patient labor and soundness of character that are found in the literature. V. Purvits (b. 1872) won international fame with his landscapes and J. Rozentals (1866-1916) also won fame in ment lines. French influence became very strong even before the restoration of national independence. Since that time the modern developments have maintained the Latvian spirit and followed the various trends of European and esp. French art.

The same is true also of sculpture in the person of B. Dzenis (born 1879) and Z. Zalkalus (born 1876), a student of Rodin. Among the leaders of the younger generation are Emils Melders, Marta Skulme, K. Zale and Arnolds Dzirkals. See Marcel Segreste, *La Lettonie,* 1930; Alfred Bilmanis, *Latvia in the Making,* 1928. —C.A.M.

**lauda spirituale.** See MEDIEVAL MUSIC.

**laughter vibrato.** See vibrato.

**laurel.** In classical art, a decorative pattern with long thin pointed leaves arranged opposite each other on a stem; used in wreath form as an emblem of honor or crown of victory. —L.T.S.

**law of frontality.** See frontality, law of.

**law of three sections, the.** See CHINESE ARTS.

**lay figure.** A mechanical figure jointed in such a way that it can be given a pose somewhat like that of a living human figure is often used as an artist's model, particularly as a support for drapery. It is like a manikin but the term, lay figure, has been applied usually to somewhat more realistic devices in which the mechanism and the joints were covered. It appears not to have been much used before the 19th cent. —G.L.S.

**laying in.** See design.

**lead glass.** See GLASS AND GLASSMAKING.

**leading note, leading tone.** See idiom B(1).

**leading seventh.** See idiom B(1).

**leaf and dart ornament.** A classical molding enriched by alternating the leaf and dart forms.

**leaf pattern.** See Lesbian leaf.

**lean-to.** (1) A structure, usually comparatively small, having a single-pitched roof with its apex against another building, or against a wall. (2) Having rafters, as a roof, sloping only one way. —J.M.M.

**leather.** The large use of leather in the crafts does not have a parallel in its use for objects of fine art, though it has served occasionally as a support for representational painting. Most of this seems to have disappeared and is only a matter of literary record. —G.L.S.

**lecythus.** A Greek oil-flask, with long body, narrow neck and small mouth, used for bath, gymnasium, and funeral purposes. Early Corinthian lecythi had a short, thick neck and cup-shaped mouth. The most beautiful vases of this type were made in Athens from 550 to 300 B.C. Their shape was cylindrical,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

tapering gracefully to the base, with a slender handle attached to a long neck and rather flat shoulder. Vases used for memorials at graves were covered with a yellowish-white slip, on which there were paintings in brown glaze or dull matt picturing home life and poignant farewell and commemorative scenes. Often purple borders were added on the garments, and green, blue and yellow color was sometimes used. The designs are notable for their flat effect, simplicity of line, and modestly monumental compositions. —W.R.A.

**ledge.** A horizontal top set into or against a wall, resembling a narrow shelf, and being usually less than twelve inches in width. —J.M.M.

**legato.** *Mus.* Smooth, connected; opposite of staccato (q.v.).

**legno, col.** *Mus.* A direction in violin playing to strike the strings with the back of the bow.

**lei** (Ch.). Sacrificial bronze vessel. Vase-like form with wide mouth and small boss-like handles at side of neck.

**leich.** See MEDIEVAL MUSIC.

**leitmotiv** (Ger.). *Mus.* The leading theme or motive (motif) repeated throughout a work. See idée fixe; opera.

**lei wen.** See PREHISTORIC ART.

**lekythos.** See lecythus.

**lemon yellow.** The pigment which carries this name is perhaps better known as barium yellow. It has a slightly greenish tinge and is pale. Chemically, it is a barium chromate and its preparation was first described in 1809. It is moderately stable, being very little affected by light but decomposed by heat at high temperatures and soluble in dilute alkalis and in dilute mineral acids. —G.L.S.

**leno fabrics.** See weaving.

**Lenox china.** See CERAMICS II.

**Lesbian wave.** An ancient Greek pattern used in architectural and sculptural works, frequently in moldings and cornices; also called the Lesbian or water leaf, or Lesbian cyma. A decorative molding the pattern of which consists of a series of heart-shaped leaves with a deeply marked midrib. (For ill. see *Enc. Brit.*, 14th ed., Vol. 15, page 926, ill. A.) —L.L.

**lettering** (verbal noun, fm. *letter* verb, to affix an inscription upon anything, fm. *letter* noun, an alphabetic character, which represents one of elementary sounds of speech. (1712 Addison *Spectator* no. 463, p. 7, "I observed one particular weight lettered on both sides"). The action or process of putting letters upon anything by inscribing, painting, gilding, stamping, etc. Also, concretely, the letters so inscribed.

Lettering is the most formal method of making an inscription. Its formality, evident alike in the forms of the letters and in their arrangement, results from the purpose of the lettering and the method of its production. By intent, a piece of lettering is meant to have maximum legibility and, usually, more or less permanence. In its production, these ends are achieved by the use of a deliberate process, which includes two main operations: (1) the making of a preliminary plan in a temporary medium to determine the letter-forms and their arrangement; (2) the completion of the letter-forms in a more permanent technique. It is this dual process which differentiates lettering from the simple and direct method of writing. In ancient times, as is evident from certain surviving inscriptions in stone or metal, the preliminary design was usually made in formal writing on the stone or metal surface with a chisel-shaped brush and red pigment and afterward completed by incising with a chisel. This use of a free preliminary rendering with a formalizing secondary technique appears to have been the usual classical and medieval procedure for all kinds of lettering. In the late 14th and early 15th cents. a great formality was sometimes introduced into inscriptions by the use of letters drawn mechanically with draughting instruments and constructed geometrically to control their proportions. There exist three 15th cent. manuscripts with designs of the geometrical construction of letters and from the same period one printed book, the diagrams of a Roman capital alphabet issued by Damiano da Moile at Parma ca. 1477. In the early 16th cent. there were published a number of subsequent treatises on the subject, of which the most important are those of Luca Paccioli (Venice 1509), Sigismondo Fanti (Venice 1514), Albrecht Dürer (Nuremberg 1525), and Geoffroy Tory (Paris 1529). Since the 16th cent. the growing volume and influence of printing has caused lettering in most cases to be modelled on the designs of contemporary printing types (type design itself being by definition a kind of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

lettering), although throughout this period there have usually appeared a few examples derived directly from classical or Renaissance inscriptions. With the modern revival of calligraphy there has also been a return to the classical method of a preliminary design in formal writing to be completed later in some more permanent technique. See J. H. Benson and A. G. Carey, *The Elements of Lettering,* 1940; British Institute of Industrial Art, *The Art of Lettering,* the report of a special committee, 1931; H. Degering, *Lettering,* London, 1929 or German edition *Die Schrift,* Berlin, 1929; E. Johnson, *Writing and Illuminating, and Lettering,* 1906. —E.F.D.

**LIGHT, CREATIVE USE OF.** Because of the diversity of the uses of light, the word light has assumed a many-sided and somewhat ambiguous meaning. To the artist light is a medium for creative expression. It is used as a physiological and psychological stimulant for inducing emotional and intellectual response. It is this aspect of light we are primarily concerned with, and its physical properties will be considered only in respect to their relationship to visual sensation.

However, in order to evaluate the use of light in the visual arts we must first understand the role light plays in our understanding of space, and the role space plays in human experience.

Everything in the outside world presents a possible threat to man's existence. Without complete knowledge of the position and arrangement of the object world in relationship to himself, man could not hope to survive. He must be able to measure distances and determine the size of objects and the speed of their movements. This necessity develops in him an acute consciousness of space.

The measurement of space is done through the medium of the sense organs. And while to some extent it involves such senses as touch, hearing, equilibrium, and so forth, it is primarily based on the sense of sight, which is the impact of light on the eye. Without light or capacity for perceiving and measuring, space would be almost negligible.

In this sense, space, and the light by which we know it, become one. And as the principal vehicle for space experience, light acquires the power to produce the same emotional response as space.

We have evidence throughout history of man's profound sense of dependency upon light. In early times it took the form of attributing omnipotent powers to light sources. There were cults of fire worshipers and sun worshipers. Even the words light and space, in the languages, suggest the important influence they had on man's habits and living conditions. The root of the word space is variously given as—power, to be successful, to be able to, to increase; and in contemporary language it invariably has connotations of comfort, security, and pleasure. The word light is variously defined as enlightenment, awareness, orientation; and the definition of the opposite of light, darkness, is equally significant—to obscure, to hide, gloomy, hopeless.

So in view of this it is only natural that man in his creative expression should attempt to imitate light in order to represent the world of space he lives in.

Light can be seen either directly, as in the case of the sun, fire, electric bulb, luminous gas, or indirectly, as a reflection. Objects

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

are recognizable to the eye because of its ability to discern differences in brightness and hue; that is, differences in light, shade, and color. These differences are revealed by the characteristics of the light reflection, refraction and absorbtion.

In a sense, the world can be conceived as being composed of innumerable light modulating surfaces or substances. Man, desiring to express himself and communicate his experience to his fellow man, recognized and progressively controlled the light articulating properties of the materials in his reach. In time his experiments resulted in the arts of painting, sculpture, architecture, photography, motion picture and stage design. All these activities are directed toward the optical sense. In all of them the control and articulation of light in its interaction on materials is of dominant importance.

In painting and graphic arts the light reflecting and absorbing qualities of pigments are utilized. One objective is to create the illusion of a three-dimension object world on a two-dimension surface.

In sculpture, clay, stone, metal, and other materials were modelled in such a way that the action of light upon it would explain its spatial extension.

In architecture, space is achieved also by the light articulating qualities of the walls. Opacity, transparency, and surface qualities all contribute to the explanation of space.

In stage design, by controlling the interplay of artificial light on the mobile reflecting screens—the actors,—and on the static screens —the props,—kinetic spatial unity is achieved.

In photography, through the optical system of the camera, the reflected lights of the objects are collected and reproduced on a photo sensitive emulsion, creating an illusion of the spatial world.

In motion picture, as in photography, light coming from the object can be recorded on a photo sensitive emulsion, but unlike photography it can in addition reproduce space in motion.

The development of man's understanding and control of light can be best observed in the study of the history of painting. Primitive drawings and paintings are the first material we have showing man's conscious ability to interpret the outside world. They are mostly in flat silhouette, and although they reveal the immature state of primitive man's visual development, they show an important, if elementary, grasping of the significance of light. The ability to recognize and crystalize the myriad light tones that are involved in the fixing of even a flat image on a flat plane was a great achievement toward the utilization and control of light.

We assume that at first man was able only to distinguish the light quality differences between objects and their background, and that familiarity with these tonal differences gradually developed into certain and immediate recognition. The light relationship between object and background became a familiar pattern of light sensation and in time man identified this light pattern as the object itself.

Not being able to control actual light sources, man used pigments as his first means to articulate and modify light. In these early representations man was entirely preoccupied with the objects of his surroundings. The bodies of animals, the shape of trees, the sun, and all the important objects of his environment, the friendly and the dangerous, had characteristic forms, and it was important to recognize them.

Of course, this does not mean that the early cave paintings are equivalent to primitive man's visual development, because his lack of experience with, and the actual lack of implements of expression (pigments, brushes) must be considered.

Cave painting, children's painting, and in fact the painting of all early cultures show this period of development. An object is represented in outline without regard for the relationship it bears to other objects or the internal relationship of its details. But as the visual perception develops further, the area of recognition becomes larger, and the interrelation of objects becomes evident as well as the more complex inner details of the objects themselves.

Visual development, the growth of sensibility to the subtleties of light differences, can be observed clearly in the paintings of the different culture periods. In this development, all culture showed a similar evolution. In the early stages of each culture, drawing and painting show one flat surface against another. As the culture advances, the paintings begin to show signs of modelling by use of light and shade. For example, the art of early Egypt, Mycenaen, Greek, Roman and Western civilizations, all represented the object world as flat and without depth dimension. Later Mycenaen, Greek and Pompeiian frescoes introduce in their respective cultures the conscious use of light and dark

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

variation to show depth and consequently space.

In Western culture, the dawn of the Renaissance found painters such as Giotto, Cimabue, and Duccio painting with sculpturesque treatment, modelling the surface by the use of light and shade. Of this period Masaccio showed the clearest understanding of the newly conceived object representation. In his paintings, color and form became closer to their actual appearance in nature. Bright colors were softened by distance. Later, Michelangelo and Leonardo da Vinci, by constant studies of the effect of light on form, brought this naturalistic rendering of the object to an even higher level.

Leonardo da Vinci's contribution was especially noteworthy. He systematically recorded and collected existing information on light phenomena. He investigated the properties of light in much the same way that his scientific contemporaries dissected and listed parts of the body. Not only did his work show a clear understanding of light as an agent in determining form and of the importance of the control of light in chiaroscuro, but he prophetically sensed other important properties, some of which later painters used and some which we are only today beginning to use, such as light mobility, aerial perspective, certain actual physiological effects of color upon the eye, tone and color contract, and the spatial value of sharp and unsharp definition.

In rendering the apparent accidental conditions of reflections, Leonardo was the first to instill in his paintings the transitory elusiveness which is characteristic of nature. But he and his school were still engrossed with the task of naturalistic rendering of the object. The object remained as the complete and sole focal point of interest. The remainder of the painting was in most cases a passive background. In the time of the early Baroque, we find a maturing of the seeds planted by da Vinci. In this period Coreggio, Titian, Veronese, and Tintoretto begin to show an acute consciousness of the power of light. They were no longer content solely with imitating an object, but were much more interested in showing the interrelationship of forms. They sensed the fact that objects were completely dependent on light, and that their paintings were little worlds of light, which they indicated by the arrangement of the object. Tintoretto actually constructed a small box in which he placed small wax figures in order to experiment and study the effects and interrelation of light on forms.

More and more light, rather than the object, was being recognized as the active and important element in the painting. But it was not until later that light began to be used as an intrinsic element for bringing together compositions. (The words light and color will be used interchangeably in this article, color being a physical phenomena directly dependent upon light.) And eventually in Rembrandt we get the actual experience of light space. In his compositions the entire surface with frequently only two or three bright spots seems to quiver brilliantly with light. When we look at his paintings, we know that the light is not confined to the bright spots we see, but that the entire surface is charged with the passage of light, and that it is latent even in the darkest corners. The object has now definitely lost its rigid mooring, and isolated independence. It is afloat in a volume of light space, maintaining its position only in relationship with other forms.

After Rembrandt we find the painters giving much more attention to organizing of light and dark areas, than to the subject matter. The paintings of El Greco, Velasquez, Ribera, and Zurbaran are violently dramatic in light arrangement. El Greco experimented with light by using clay figures in a small box. There is now an unquestionable realization of the importance of light as the organizational element in the painting. Gone is the slavish fidelity to actual appearance of objects. Shapes and lines are distorted, detail is frequently omitted altogether, and in general the significance rather than the appearance of an object is sought for.

Prime attention is given to light relationship between objects, and the paintings acquire a spatial depth that is no longer solely dependent on artificial devices such as perspective and size relationship, but rather upon the skillful relating of the dark and light picture areas.

And still, light was not completely liberated from its bondage to form. For despite distortion and lack of detail there remained a definite structural shape in object representation, which does not disappear until the time of Turner and Constable. In their work, forms become almost dematerialized. This is especially true in the later landscapes of Turner where the forms become dissolved into translucent and luminous space.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

This marked the highest pinnacle man had achieved in the conscious control of objective light representation. The almost complete dissolution of form was the keynote of freedom for the Impressionist painters. They realized that the sensation of space could be produced by stimulating the eye by light pulsations alone. This was in recognition of the fact that the experience of space is conditioned by the neuro-muscular structure of the eye.

However, in practice they were confronted by the same problem which centuries of painters before them had tried to solve. The problem was a fundamental one concerning the nature of the eye. When one color pigment is placed over another one, the light given off by the under pigment is subtracted by the color placed above it. This is true even if the colors are transparent. The result, of course, is a diminishing of brightness. Since the impressionists were concerned with faithfully reproducing the brilliancy and vividness of the outdoors, this presented a stumbling block. The difficulty was solved by placing the different colors side by side in close proximity to each other. The colors are then combined by the eye into a single additive mixture, the final result being the added brightness of all the colors.

In the past there had been many painters who had intuitively grasped the effects of these additive and subtractive mixtures. This accounted for the remarkable radiance and brilliancy in the paintings of Fra Angelico and Fillipino Lippi, and Botticelli, as well as the almost unearthly luminosity in the skin coloring of Rubens. But the theories of the impressionists differed from these painters in that they were directly influenced by the scientific discoveries of their time. The findings of Helmholtz and Chevreul were consciously exploited by painters like Monet, Signac, and Seurat. The discovery and development of photography also contributed greatly to the growing consciousness of the inherent power of light. In photography light was the active and dynamic element. It is most interesting that in the short period of one century, the evolution of photography arrived at a stage almost identical to that of painting. In photography the importance of light as a technical agent was obvious from the first, but its importance as a medium for giving visual space experience developed apace with the late stages of painting. The photogram in photography can be compared with the final results of cubist analysis in painting. It liberated photography from the limitations of realism and presented the opportunity to observe the action of light and shadow in its most refined and subtle interrelationships.

The future is sufficiently revealed to warrant certain predictions. Light itself is assuming its place as the medium for a new art. What has been dimly perceived throughout our cultural history and has been attempted in various forms such as in the stained glass windows and the experimentation in stage lighting is now a reality.

Three factors made possible the work in this new medium. First, scientific progress supplying new data concerning the physiological and psychological attributes of the eyes and vision; technological progress, the invention of electricity and new light sources, and the many devices for controlling these sources, switches, rheostats and so forth; and thirdly, environmental conditioning. For the technological advances had introduced new elements of visual stimulus into the every-day life of the people. The blinking electric bulb, the brilliancy and color range of the neon light, both used extensively by the advertiser, made people more receptive to experimentation with these daily phenomena.

All these developments opened the way for a new form of visual expression—the use of light as a primary medium in itself. In creative expression in the past, light has been the auxiliary medium for revealing the qualities of other media and materials, such as, color pigment, clay, glass, paper, pencil, pen and so forth. Now cognizant of the fact that light in itself contains the power of awakening strong emotional reaction, certain artists started to use it as a plastic medium.

In this progressive work, probably the first form is the motion picture. Here for the first time light is used, not as an agent, to make articulate a controlled two-dimensional screen (such as painting or the photograph), which in reality modifies the light which falls upon it, but conversely the light which falls upon this blank white screen is in itself the articulating factor. The screen no longer is used to modify the light. The projected image, with all of its inherent power to stimulate emotional reaction, is simply a controlled succession of light rays of various intensities illuminating the even white screen. The blank screen is now entirely dependent on the light for its meaning. The screen, then, is not limited to one characteristic image( as in the painting) but thousands or millions of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

images. All organization is now mobile light and shade relationship.

With these new elements available, the most subtle and refined manipulation and control of light became possible. Many contemporary artists contributed to this work. Probably the earliest who tackled the problem was the Russian composer, Scriabin, who in 1911 synchronized his composition of *Prometheus,* the poem of "fire," with a color light play.

Viking Eggeling's *Diagonal Symphony* (1919) was the first abstract film based entirely on the plastic treatment of light. Shortly afterwards, Hans Richter (*Prelude and Rhythm,* 1921) and Walter Ruttman (Opus I, II, III) made similar films. Moholy-Nagy's film *Black, White and Grey* appeared in 1930.

In 1922 Hershfield Mack wrote a color sonata. This sequence of color and form projected on a screen was in symphonic notation. This instrument was called a color organ.

Thomas Wilfred and Alexander Lazlo made further developments in the color organ. In the color organ of Lazlo, prisms, lens and colored filters are revolved in a complicated interplay, while all of the elements, the speed of the movements, light intensity, color mixture, etc., are played directly on a keyboard. There has been additional experimentation in the use of projected light directly in painting and also in sculpture but much of it is still in a formative stage.

It would be well to acknowledge here the indebtedness the entire movement has to Adolph Appia. As early as 1895, in his book *Music and The Stage Setting,* he clearly stated many of the basic principles of light which the foremost present-day exponents of the art recognize.

The word done in the exploitation of this medium has not been extensive but is of great significance, for it indicates an attempt to sensitize the vision so that it can respond to abstractions of form and color, with the same pleasure and awareness as the ear to music.

Eventually a heightened sensivity such as this cannot but have the most direct influence on all of our entire controllable environment. Much of this is, of course, unpredictable, but e. eg., the architect in planning a home may have to consider not only room and convenience areas as he does now, but light areas, in which the subtle reactions of the dweller to the fluctuations of light in various parts of the home would have to be considered and solved.

There are increasing evidences that people are becoming more and more aware of the possibilities of light as an expressive medium. In recent years the use of light in world fairs and similar large exhibitions, has long since departed from the simple task of illumination and has been used to create veritable three-dimensional color panoramas. Another use stemming from ancient times, but now developed to high degree, is the pyrotechnic or fireworks displays. The dramatic theatre has for a long time used light purely for evoking emotional effects and many experimental plays have been produced, containing no scenery but depending entirely on the manipulation of light and color to achieve mood and situation.

Difficult as it is to predict the future of the art of light, we can without knowing the exact direction and form it will take, prophesy for it a role of great importance.

It has captured the imagination of many creative artists. One of the artists L. Moholy-Nagy, who has worked extensively in the light medium, writes—

" . . . a future in which light displays of any desired quality and magnitude will suddenly blaze up, and multicolored floodlights with transparent sheaths of fire will project a constant flow of immaterial, evanescent images into space by the simple manipulation of switches, . . . "

As has been pointed out, the potentiality of light as a plastic medium has until now merely been suggested. In the future lies its maturing. See COLOR; lumia; clavilux.

**light tracks.** See PHOTOGRAPHY.

**lily.** In classical art, a conventionalized ornament based on a lily form, having a petal ending in a spiral at each side of the central stamen lines. —L.T.S.

**lime.** This is chiefly known in the arts as the principal ingredient of plaster and an important factor in the process known as fresco painting. Lime oxide is made by burning limestone, marble, or chalk to drive off carbon dioxide. This mixed with water becomes a lime hydrate or putty and, combined with suitable amounts of sand or other granular ingredients, forms the traditional lime plaster.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Pigments mixed with water and applied on this are held in place by changes in crystalline character as the lime becomes a hydroxide and later a carbonate. —G.L.S.

**limited access highway.** See CIVIC PLANNING.

**limners.** See EARLY AMERICAN ART.

**Limoges ware.** See CERAMICS II.

**limp.** *Book.* Limp binding, limp boards,, limp covers, are all terms used to describe a book bound with covers that readily bend without cracking; and further described as limp leather, or limp cloth—seldom, if ever, applied to paper covers. The covers may be lined or not. —H.E.S.

**line engraving** (an intaglio process). Line engraving is older than etching, having been used by armourers and jewelers before the 15th cent. It reached its height as a print process in the days of the artists Dürer and Schongauer.

In this process the metal is cut away with a burin, instead of using an acid to eat out a line as in an etching or instead of using a metal point to raise a burr as in a drypoint. It is much easier to make a straight line with the engraving tool than a curved one. These characteristics giving the engraving a stiff angular quality, although the lines have a clear regular perfection.

Sometimes the print is made by using dots of various sizes and depths instead of using lines. This is called **stipple engraving.**

Modern print makers have brought out most effectively the stiff angular beauty of this process. The great modern French engraver, Laboreaur, and the Czech, Bouda, have done this esp. well. —K.K.

**line etching** (an intaglio process). Line etching is one of the most distinguished of the graphic processes. Etching was used by jewelers and armorers before the 15th cent. for decorative purposes. In the 16th cent. line etching was used as a short cut to engraving and became popular for its freedom and quickness. Among the first to use it was Albrecht Dürer (1471-1528), the great German wood and copper engraver.

Line etching is one of the intaglio processes. The design is carried by the deep indented parts of the plate instead of by the raised parts as in **relief printing.**

Copper, ground and polished to mirror brightness, is the ideal metal to use, though zinc and occasionally other metals are sometimes used. The plate is heated and an etching ground made of wax asphaltum and other ingredients is dabbed or rolled on the surface. The plate is held in a hand-vise and smoked with a taper. The ground acts as an acid resistant. The drawing is made on the grounded plate with a pointed steel stylus that breaks through the ground coating to the copper. When the plate with the drawing scratched through the ground is laid in an acid bath, the acid will attack and dissolve the copper wherever a stylus line has laid the copper bare. This is the process of biting the plate. The three most common acids used for biting are nitric, Dutch mordant, and iron chloride. Certain areas are exposed to the acid longer in order to make the line deeper and blacker while other areas are **stopped** after a short bite with a varnish called the **stopping out varnish.** The varnish and ground are removed after biting and the plate is ready for printing.

The entire plate is covered with the etching ink. The ink is wiped off the surface with tarlatan and the palm of the hand, leaving ink only in the lines. A delicate film of ink also remains on surface of the plate which helps to give etching its peculiar charm.

The etching press consists of two heavy iron rollers with a flat iron bed between. The inked plate is laid face up on the bed; dampened etching paper is laid on it, followed by a piece of blotting paper and a felt blanket. In passing through press, the rollers force the soft damp paper down into the lines, producing the characteristic plate mark, the smooth pressed surface and the raised lines of an etching. The damp proof is now flattened and dried between blotters and is ready for matting. —K.K.

**line of direction, of sight.** See PERSPECTIVE.

**linear.** i.e. forms expressed prevailingly by lines. (The term has been introduced into our aesthetic vocabulary by Henrich Woelfflin. who uses it in his *Kunstgeschichtliche Grundbegriffe* (1915), [*Principles of Art History,* New York, 1932] in contrast to "painterly".)

It describes an artistic expression in which objects or ideas are rendered by circumferential lines. Yet the use of lines alone does not suffice to describe a painting or a drawing as linear. These lines must be made significant by the absence or at least the subordination of light and shadow under the linear

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

forms. Accordingly, color too is of secondary importance in linear rendition. The term can be used in a derivative sense for sculpture.

Since there are no lines but only masses in nature, visual conception furnishes the human eye with an abstraction which offers the designer a means of simplified statements for visual facts or for the visualization of ideas. The strongest emphasis is given to the contour. Leon Battista Alberti in his second book on painting and Friedrich Schiller in his poem *Der Künstler* (The Artist) follow Pliny's (xxxv, 15) aesthetics when they ascribe the origin of design to the tracing of a line around the shadow cast by an object.

The relationship of lines to each other implies other aesthetic qualities: the clarity and evenness of statement calls for a decorative arrangement of lines. Linearism has consequently, a tendency toward the decorative which may be observed e.g. in the Greek vase painting of the 5th cent. (Sosias, Euphronios).

It must further be stressed that it is the relative isolation of each line which makes a design linear, while the fusion of lines into groups tends toward a painterly effect. Evenness of muscular pressure applied to drawing creates a linear form, unevenness of pressure resulting in changing darkness and discontinuity of form which create a painterly line quality.

It is, therefore, a quality of mental control and an ability for abstraction from reality and from self-consciousness; it is a tendency toward objective statement which is found in artists who express themselves in a linear style.

The simplicity and clarity of lines appeal particularly to periods or individuals whose aesthetic ideals aim toward conciseness of statement. By its method of abbreviation the linear style is esp. capable of denoting not only visual facts but also ideas or abstract notions. In the latter case the linear design becomes an ideogram or a hieroglyph. We find linear expression favored in Egyptian art, in Greek art down to the 4th cent., in medieval painting, in early Renaissance art, in the art of the neo-classical era, in contemporary abstractions and modern classicism.

Summarizing we may say: the linear style implies a tendency toward rhythmical clarity, decorative balance, and objectivity, all of which are characteristic of *Seinsstilen* ("styles of being", a term used by Woelfflin) in contrast to *Werdensstilen* ("styles of becoming") which latter usually tend toward the painterly expression.

The theory of the linear style is to be found wherever artistic tendencies stress the before mentioned qualities. We have already spoken about Alberti as the early Renaissance exponent of linear aesthetics. With Leonardo da Vinci the problems of light and shadow become more strongly emphasized and from then on these problems counterbalance the emphasis on linear treatment. The full impact of the linear theory is to be found in the neo-classical era, esp. in the writings of Kant, Schiller, Goethe, etc. Hogarth's "beauty line" in his *Analysis of Beauty* (1753) stands at the beginning of English linearism theoretically as well as practically. The last important revival of the neo-classical linear theory is developed in the essay *Das Problem der Form in der Bildenden Kunst* (1893, 2nd ed. 1914) by the German sculptor Adolph von Hildebrandt. This essay has influenced Woelfflin's basic theory of the linear which was quoted in the beginning. —A.N.

**linear elements.** See PAINTING.

**linearism.** See linear.

**linear perspective.** See PERSPECTIVE.

**linen.** (1) The principal use of this material has been as an accessory in the arts and probably its greatest use has been as a support of paintings. Since the late Egyptian dynasties when it served, along with thin panels of wood, as a material on which mummy portraits were executed, it has had this kind of utility. With the development of painting in the 16th cent. and, more particularly, in the 17th cent., linen became the principal painting support, and the name has become practically synonymous with canvas. It is made from the fibres of the flax plant and, like most of the textile fibres, is largely composed of cellulose. It can be formed into a firm thread capable of being bleached white and, when used as a textile, of taking a variety of colors by dyeing. (2) *Book*. A woven material made of lint or flax and loaded or filled. —G.L.S.

**linen weave.** See weaving.

**lingam.** Phallic symbol of divine power of creation.

**ling-chih** (Ch.). The fungus (q.v.).

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**ling mai** (Ch.). Literally, feathers and furs. A major school of painting in which birds and animals are the subjects.

**lining.** *Book.* Linen linings are strips of linen on the inner folds of a section sewn through with the section and pasted down. Lining papers are the same as end papers. Also applied to the process of lining the back with brown paper or leather before covering.
—H.E.S.

**linoleum.** From *linum,* the Latin word for flax (the plant which produces linseed oil) and *oleum* meaning oil, is a floor covering made from cork ground to the fineness of flour, color pigments and a linseed oil "cement" which holds the particles of cork and color pigments together. —B.E.J.

**linoleum cut.** See PRINTS AND PRINT PROCESSES.

**linoxyn.** Though rarely used in the technology of the arts, this term is common in general paint technology. It stands for the fully dried and hardened film of linseed oil.
—G.L.S.

**linseed oil.** Although other drying oils, that is, oils capable of hardening into a firm film through the addition of oxygen to the molecule which forms the oil fluid, have been used as painting mediums, the oil of linseed has undoubtedly been the principal one taken for this purpose. Such oil is expressed from the seed of the flax plants, and the better grade for artists' paint comes from cold pressing. Unbleached, this has a bright golden yellow color. It is refined by washing or by settling or by chemical methods. Bleaching is best done by exposure to sunlight. The oil of linseed contains mixed triglycerides of linolenic, linoleic, oleic, and stearic acids, together with small amounts of other acids. It has been usually supposed that the finest oil comes from India and is known as Calcutta oil. Its history is indefinite in the past of the painting art. It was known as early as the 8th cent. but had its greatest use as a medium beginning at some time in the early 15th cent. —G.L.S.

**lintel** (Med. Lat. *lintellus,* head piece for a door or window). The horizontal top member spanning an opening, as of a doorway or window. —J.M.M.

**lion.** See SYMBOLISM IN FAR EASTERN ART.

**lip reed.** See ACOUSTICS.

**Litany.** An ancient form of prayer in which the priest lead and the people responded.

**LITERARY CRITICISM.** Of all the branches of criticism, that of literature is at once the most understandable and the most confused, the easiest to practice and the least rewarding as a guide. The resolution of this seeming paradox resides in the nature of the material that is here subjected to criticism: works of literary art, as compared to works of the other arts, are both more obvious and more complex.

Due to the first of these qualities—the obviousness of literature—literary criticism is temptingly easy to practice and deceptively easy to understand. Where a large portion of the other arts is, strictly speaking, meaningless to many persons, poems and stories, essays and dramas, convey some kind and degree of meaning to almost everyone. Consequently, literature being by far the most familiar of the art forms, criticism of literature appears as a natural and simple exercise of judgment upon materials that are accessible to everyone.

Due to the second of these qualities—the complexity of literature—literary criticism is in fact an intricate and delicate enterprise, and one that is almost always accompanied by confusion. Works of literary art are complex in the sense that they contain a plurality of values and so have different meanings for different readers. Put differently, this is to say that literature is the most impure of the arts, because there is here the greatest intrusion of reference foreign to the artistic form, and the highest ambiguity of artistic meaning. This of course entails that works of literature lend themselves readily to various interpretations, with the result that the same objective work of art will serve as stimulus to several quite different subjective acts of appreciation. Since it is, fundamentally, the work-as-appreciated that is criticized, the effect of this ambiguity of value and meaning upon criticism is obvious. Literary criticism has suffered greatly from this fact: different critics have found in literature different value and have lent to literature different purposes—have subscribed to conflicting aesthetic doctrines—and have done this unconsciously. Then, they have insisted that the value they find is unique, and all others spurious. And criticism degenerates into debate. Hence, the first step in an intelligent

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

consideration of literary criticism is the thorough recognition that literature is a locus of many values. And the prime task facing the philosophical analysis of criticism is a discussion of these values, and of the various schools that have developed from them.

The general function of criticism can be summed up as consisting in the *evaluation* and *interpretation* of works of art. The function of the critic is to act as a mediator between art and the public: it is the critic's proper business to advise the public as to what is good and what is bad in art; and then, further, to aid the public toward an accurate and sensitive appreciation of art. Of course, objection can and will be made that this is to endow the critic with the tasks and powers of the censor and the educator, and that these do not properly belong to the critic. This is to adopt a thoroughly dilettante attitude toward both art and criticism: an attitude that can be defended only on the contention that art is both trivial and insignificant, incapable and unworthy of being accurately evaluated and interpreted. If art is a serious enterprise, then it certainly has some public function. And if art has a public function—if art is a matter of individual and social import—then there is a place for the critic. This place is to distinguish good art from bad; to prevent bad art from being foisted on the public; and to aid this public toward the appreciation of good art.

Within the field established by this basic agreement, there occur the differences of opinion which give rise to the various schools of criticism. Granting that art is the product of a serious human activity, with a definite nature and function, there have existed legitimate disagreements as to what this nature and function are. The act of evaluation obviously demands a frame of reference: to judge the worth of an object, it is necessary to appeal to some criteria; and these criteria can themselves be established only on the basis of what the work of art intends to be and to do.

So literary criticism has its point of departure in some aesthetic doctrine of the nature and function of art, even though this theoretic background be unrecognized by the critic. Criticism, admittedly or not, estimates the beauty of works of literary art. So critics will differ basically in their estimates as they differ in their opinions as to what makes things beautiful. There are four general interpretations of art that have been of special historic significance; and there are four corresponding sets of artistic criteria, or frames-of-reference for the evaluation of art, that have largely constituted the arsenal of practical literary criticism.

(a) The *revelatory* aesthetic doctrine and critical dogmas. This school is based on the general position that *art is an imitation;* it holds that art reveals the essential truth about the antecedently real. Of course, there is wide disagreement as to the nature of the antecedent reality that art imitates: specific imitationist schools vary from subjective impressionism through "factual" realism to objective idealism. The core of the aesthetic doctrine is the thesis that art has a reference beyond itself. Critical schools based on this doctrine tend to evaluate art in terms of the subject-matter it imitates and the success achieved in exhibiting this subject.

(b) *Formalistic* aesthetic doctrine and critical dogmas, based on the general position that art is essentially a creation, or a "making". This theory interprets the work of art as being primarily the imposition of form upon matter; the artist takes the mere material of his craft, and he creates from this an object of formal beauty. The critical schools that evaluate art from this frame of reference emphasize values of structure and composition; the work of art is treated as an end in itself, and the artist is judged for his success in making an object that is beautiful in and for itself, with no values borrowed from without.

(c) Aesthetic theory of *expressionism* and derivative critical groups. The central tenet of this theory holds that art is an expression of the artist's emotions and sentiments, as evoked on a particular occasion. The work of art records these sentiments. There are again divergent schools which all accept the fundamental position of expressionism, with romanticism as perhaps the most famous. Expressionistic criticism is loose and inchoate, as its chief criteria must be those of *passion* and *sincerity,* both of which are difficult to apply and measure.

(d) *Moralistic* aesthetic doctrines and critical dogmas. This movement can be more readily identified to the modern reader through its most recent specialized form: the sociological interpretation and criticism of art. All such theories hold, primarily, that art is a medium for fashioning the beliefs, attitudes, and habits of people. That is, art is a formal structure that has a peculiar ability to influence those who behold it. Consequently, it is the function of art to instill into the popu-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

lace a correct and healthy set of opinions. Special schools of moralistic theory and criticism differ according to the fundamental beliefs behind them, and so vary from catholic to communistic. All have in common the intention of judging art by the criterion of its propaganda value: to be good, art must carry the right moral or lesson, and it must indoctrinate its audience quickly and thoroughly.

Before discussing in more detail the actual critical methods and practices of these different schools, there are several remarks concerning them all simply as schools that need to be made.

In the first place, it is most important to emphasize that every one of these aesthetic doctrines has its just measure of truth. Art is in fact a locus of many values, a complex of several characters; and each one of these values or characters can be criticized and judged. Hence, each aesthetic thoery is a partial truth, and each method of criticism can but partially exhaust the possibilities of the art work that it seeks to evaluate.

The natural and expected result of this aesthetic fact is that critics, and critical schools, find it all but impossible to be consistent. A critical group bases itself on the correct recognition of one type of aesthetic value, and announces its determination to judge works of art as they exhibit this value. But then, in the act of aesthetic appreciation, a critic of this group becomes aware of another type of value in a work. This value is not, and cannot be, recognized by him as an official critic; but it is recognized, and can not be denied, by him as a person. So it inevitably influences his evaluation of the work; and he must broaden his critical frame of reference to include this value, or must distort his criticism so as to honor it without acknowledging it.

Finally, this emphasizes again the fact that it is the prime responsibility of a conscientious critic to remain always aware of the aesthetic principles upon which his practice is based, and to submit these principles—as well as their application—to periodic scrutiny. Criticism is a type of measurement; and as such, the measuring tool is prior to and of at least equal importance with the object measured. Hence, the critic must remember not only to search out the exact quality of the work before him, but also to search out the meaning and accuracy of the standards he applies to the evaluation of this work.

We can turn now to some consideration of the critical standards and techniques employed by each of these schools.

(a) *Criticism based on the content, or external reference, of the literary work.* Such criticism regards the work of art as essentially a report of something existing independently of the work. Obviously, then, there will be two fundamental criteria available to critics in their evaluation of any particular work. First, the work can be judged on the basis of the worth or value of that which it represents. Secondly, it can be judged as a more or less adequate report of this subject-matter.

When art is referred to as *great*, and is praised for its "nobility", "depth", or "importance", it is being evaluated on the first of these bases. Such criticism depends primarily upon the fact that art is significant, in the primitive sense of signifying, or pointing, beyond itself. Thus, the standard of greatness in art is one that measures the work of art in terms of the scope or dignity of its subject-matter. This reportorial aspect is probably the most obvious quality of art, and this element has always weighed heavily in criticism. The most naïve and spontaneous artistic judgments are our statements that a book has a "good story" or that a painting is a "fine likeness". And much of the most sophisticated criticsm consists only in a refinement and elaboration of such judgments.

Historically, criticism of this general character has been practiced under the guise of many specific schools, which differ so acutely and so loudly among themselves that their common nature is all but lost. These schools depend upon, and arise from, divergent interpretations of what is independently real and so the proper object of artistic exploitation. Generically, all such criticism evaluates and interprets art as a record of reality; specifically, the criticisms vary as the critics hold different opinions of the nature of the real. The most familiar critical schools of this type are the *idealists* and the *naturalists*, or *factual realists*. The idealists, of course, attach faith to a realm of perfected ideal essences, more or less akin to the Ideas of Plato and Schopenhauer. They hold that the function of art is to reveal this realm, and that the artist must first possess the vision to grasp these essences, and then the technical skill to exhibit them clearly to men. Such criticism has encouraged an intensive exploration of the realm of values, and has promoted much art of an inspirational nature. It has

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

also, of course, fostered a good deal of dull and platitudinous art, and has sometimes had the unfortunate effect of submerging the art work in its subject matter.

Naturalistic, or realistic, criticism, depends upon the metaphysical hypothesis that only physical particulars are real. It says that literary art should give a factual report of the details of objects, events, and situations. Critics of this group demand of art a minute attention to physical data, abstention from generalities and abstractions, and a profound adherence to the laws of cause and effect. This criticism tends very strongly to deny any of the so-called higher interests and motivations of man, and usually reduces human behavior to the most primitive appetites: sex, wealth, power, pride, and jealousy. The effect on literature has been salutary in that it has torn away the false platitudes of idealism, and has encouraged a facing of the facts; it has been unhealthy in that it has blinded men to some real facts of human nature, and has reduced the perspectives that artists need.

Two other sufficiently familiar critical schools of this type are the *sur-realists* and the *impressionists*. The first insist on the falsity of all the phenomena of "ordinary" consciousness, and strive, through art, to achieve and reveal the "true" reality that lies above and beyond this conventionalized shadow. Impressionistic criticism emphasizes the Heraclitean doctrine of flux, sees all things as always changing, and finds the value of art in the recording of these ephemeral moments.

The first tendency of all of these specific schools of imitationist criticism is to evaluate works of art in terms of their content; and here, the standards used will vary between groups. But, in the second place, all such schools also evaluate works of art as a medium of expression or communication: i.e., works can differ as to the clarity and force with which they exhibit their subject, and so can be of different value in this respect. The criteria that are used in this phase of evaluation are common to the various schools, since they are meant to measure the same characteristic simply used to different ends: i.e., they judge the efficacy of the work in revealing clearly and convincingly some vista of the real.

(The most important of these criteria are: truth, clarity, intensity, range, extensity, organization, structure, meaning, coherence, compactness, unity, variety [q.q.v.].)

(b) *Criticism which centers around the purely formal or structural aspects of the work of art.* Such criticism, a development of the aesthetic doctrine that beauty is form imposed upon matter, regards the work of art as essentially a composition of material parts into a formal whole. Here, the artistic process is interpreted as the exercise of a technique which produces aesthetic value from material that is only potentially beautiful; it does this by molding the matter of its craft into a pattern or design that is inherently pleasing.

This type of criticism arises from the recognition that works of art are products of craftsmanship; that they are brought into being by operations performed upon materials and resulting in the creation of a design that will attract and hold attention. The directions then taken by formalistic criticism are, first, toward a study of the structural principles of an art form, and, second, toward an analysis of "acceptable" or "approved" types and styles.

The first path of inquiry is meant to terminate in the enunciation of the rules that must be satisfied if a work of art is to be successful. That is, the effort here is always and unavoidably to reduce art to a science: to achieve a position where the necessary and sufficient conditions of beauty can be determined and set forth for a certain art form. By far the most familiar case of this is the attempt at complete formalization made by the French tragedians; but any classicism is a case, more or less thorough, of this enterprise. The attempt is made to say, once and for all, "follow this path and success will crown your efforts, turn from it and you fail".

The second line of formalistic investigation has consisted, historically, of a steadily increasing discrimination within the various art forms. Literature, or a literary art, becomes poetry and prose; these in turn become tragedy, comedy, lyric, romance; these are broken down into yet more finely discriminated classes; and then, finally, the various styles in which these forms have been developed by different individual artists are dissected and evaluated.

Both the salutary and the malicious effects of formalistic criticism are theoretically obvious and historically familiar. Such criticism has performed services of great value in clarifying the structural elements of art, in analyzing the principles of design, in establishing certain rational and healthy artistic

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

"standards" or "models", and in refining our awareness of the subtle features and differences of works of art. Like any other human enterprise, art demands continuity, and the critics of the various formalistic schools have done much to assure this. Such criticism tends to establish types or models; that is, it produces accepted forms of beauty and value. And in doing this, it promotes continuity, because it establishes ideals and techniques that will be passed on from one generation of artists to another.

Conversely, criticism of this type has an unavoidable tendency to discourage change, and so to inhibit the development of new art forms. The models and rules once established by a critical school come gradually to dominate the artistic endeavours they are supposed to guide, and so to thwart the production they are meant to further. The history of each school of formalistic criticism and art has been the same: birth in the discovery of a new art form; maturity through a constantly progressing exploration of the possibilities of this form, until all of its subtleties and refinements have been exploited; senescence in dull mediocrities and unintelligible preciosities. The same cycle can be traced in only to many historical cases.

Fortunately, the positive values of formal criticism outlast its weaknesses; and this simply because, though models and rules may be discarded, the advances in technique and in style that such criticism exposes are permanently at the disposal of all future artists. The refinements of style and the more acute consciousness of detail that such criticism brings may be abused and so fall into disrepute; but they remain, and can be properly employed by artists of a later and healthier movement.

In the course of literary history, and coincident with the development of literature as a fine art, there have arisen many different schools of formal criticism. They have shared a common interest in the form and structure of literary works: i.e., in the organizations that can be wrought with words, sounds, sentences, and meanings. Consequently, they have all criticized literary works from the point of view of craftsmanship and technique. They have instinctively held that literary worth is a function of skill in the arrangement of elements; and so they have praised those works which seemed to them to exhibit a successful use of design. They have differed with respect to the forms that they have valued, which is to say that they have had divergent preferences and have explored in various directions.

Throughout these developments, there has been one criterion that constantly reappears in different guises: that of *unity in variety*. This principle has been so permanent because it merely is a statement of those objective conditions which will satisfy the most basic and persistent of our subjective aesthetic demands: that our attention shall be kept interested, but shall not be exhausted. In these terms, the demand for variety in artistic pattern is the demand for constantly new elements, or organizations, that will revive and stimulate aesthetic response. Conversely, the demand for unity is the demand for a pattern or structure that will bind these various elements together and facilitate our ready and easy grasp of them as a whole and as one.

Thus, the inevitable direction of all classicisms—of all schools of artistic structure—is toward a constant development of a particular form into all the richness of detail that this form can support before unity of pattern and purpose is lost. Schools of formal criticism all start off with a severe austerity: purity and simplicity of form are praised above all, and any tendency toward elaboration of structure is condemned as "decoration". This corresponds to the primitive epoch of artistic schools. The period of maturity and influence of such critical schools consists in the gradual exploration of all of the refinements and subtleties of which the particular form is capable. Here, the unity of form is covered with a vastly greater wealth of detail, and the form is treated as a skeleton to support the living richness of the artistic matter. Finally, such criticism degenerates into the inane praise of subtlety as an end in itself. Here, the detail of the work completely supersedes the structure, and the work ceases to be an intelligible vehicle of meaning.

(For the more specific criteria employed in formalistic criticism, see the following: harmony, proportion, balance, richness, purity, clean, coherence, clarity, strength, looseness.)

(c) *Impressionistic or romantic schools of criticism.* Expressionism is the most vocal and the least articulate of all aesthetic theories, and the same is true of the critical doctrines and writings that arise from this theory. This remark is *not* meant as a condemnation and utter rejection of expressionistic aesthetics and criticism: expressionism,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

in its insistence that art reflects the feelings and emotions of the artist, has hold of a real and valuable truth. But the remark *is* meant as an indication of the necessary limitations of expressionism as a basis for explanation and criticism: such a doctrine defines the work of art by referring it to the artist's sentiments and intentions; and since these are utterly private, discussion of the value of the work, by anyone other than the artist, becomes, at best, a dubious enterprise. In honesty, the most that a critic can here say is, first, that a work seems to him to reflect, or to be a fine expression of, a feeling that the artist has had; and, second, that this feeling is itself a healthy and interesting reaction to some certain aspect of the environment.

Of course, this second judgment is extraneous to the expressionistic doctrine; it judges the work by reference to an external world that it represents, even if indirectly. Hence, such evaluations are condemned by strict expressionists, and those who make them openly, as Tolstoy, have ridicule heaped upon them. In fact, however, such judgments always creep into expressionistic criticism, though surreptitiously. It is all but impossible to attend to a person's emotions and reactions purely as such: we spontaneously approve them as fitting and proper, or condemn them as irrelevant and indecent, to the situation which aroused them. The critics of expressionism have proved no exception to this human rule, and have passed such judgments. In so far as they do this, their criticism becomes of the first type discussed, where the work of art is regarded as a report; but their criticism of this type is usually quite shallow, as they have no coherent imitationist theory in terms of which to couch their judgments, and so their evaluations are purely personal and impressionistic.

When expressionistic criticism stays within its avowed province, it concerns itself only with the first type of judgment mentioned above. As J. E. Spingarn has put it, the critic only asks, "What has the poet tried to do, and how has he fulfilled his intention? What is he striving to express and how has he expressed it?" Hence, all expressionistic criticism is written in terms of three basic criteria: *passion, sincerity,* and *vividness.*

Passion is here used, perhaps unwittingly, almost in its primitive sense of subjection to and dependence upon that which is external to the self: it is used to measure violence of reaction. An artist works with passion, and exhibits it in his creations, when he is completely dominated by the environment, carried away beyond himself, and responding not with intelligence and will, but only with a powerful emotion. Hence, to say that a work of art is highly passionate, is to say that it is the record of an intense and violent reaction on the part of the artist. Passion is valued and praised because it indicates that the artist has *felt* strongly; and this in turn is supposed to guarantee that the artist has something new and different to say. The absence of passion—calmness or aloofness or tranquility—is deprecated on the ground that this means that the artist has not really felt anything, and that the work is merely a cold record of matter of fact.

The criterion of *sincerity* is used to indicate that the artist is reporting truly his reactions to his environment. The expressionistic attitude would seem to be that the artist has no obligation to seek a "true" or "correct" interpretation: he has only to state as vehemently as possible his own spontaneous response. The criterion of sincerity then means that the artist has reported what he "really" felt, and has not colored this by any effort to accommodate the opinions of others, or even his own previous attitudes. Sincerity is obviously a valuable trait in art; but it can equally obviously be abused, and made to excuse hasty and careless work, on the ground that this is "what I felt".

The two criteria hitherto discussed, those of *sincerity* and *passion,* refer to the relation between the artist and his work: i.e., they evaluate the work of art as being a more or less faithful and adequate manifestation of the artist's feelings and intentions. The third common standard of expressionism, that of *vividness,* refers primarily to the relation between the work and the audience: i.e. it seeks to evaluate the relative success of the work in conveying its content and meaning to the people who encounter it. A work is vivid to the extent that it promotes a quick and facile grasp of itself; and vividness is valued in art because it helps to clarify, to make external and public, to *express,* a content that was originally private and subjective.

In summation, it should be said that critics of the expressionistic school have on numerous occasions performed services of real value in fighting against a prevalent classicism, and in freeing art from a narrow

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

set of rules. On the other hand, such critics have done art a disservice by sponsoring and even encouraging artists to scorn all rules and principles, to deny all responsibility to anything objective, whether the real world or the real audience, and so to recognize no standards but their own whims. In this respect, classical and expressionistic criticism are invaluable foils to one another, and periods of real artistic merit always exhibit a balance of these creative and critical tendencies.

(d) *Criticism based on the moral significance of the work of art.* Criticism of this type is of far less aesthetic or literary interest than the three types already discussed, since it has no interest in the work of art apart from the effect that this makes on the audience. Critics of this school are concerned primarily with the content of the work: its subject-matter and the manner in which this subject is presented. It is only secondarily, and to a much lesser degree, that they are interested in those formal aspects of the art work which make it an effective carrier of its message.

This kind of criticism is based upon the conspicuous fact that art does have what we would now call a propaganda value and function. It has been vehemently maintained that art is not intended to serve the purposes of propaganda—to mold the opinions of people—and should not be viewed or criticized from this point of view. But the fact remains that art *does* have a propaganda effect; and so long as it does this, people are going to be intensely interested in the message that art carries, and the direction in which it tends to influence opinions. Hence, moralistic criticism has been practiced as persistently as it has been deplored, and probably always will be.

The body of such criticism has been as various as the beliefs that men have held and the doctrines that they have defended. Historically, critics of the moralistic school have been of the greatest importance: they have determined artists to develop some themes and neglect others, and they have cultivated in the reading public the literary tastes which they regarded as "right" and "healthy". The chief value of such criticism has been to promote a close relation between literary work and significant contemporary issues. That is, such criticism simply espouses the common-sense recognition that art has a content, takes up a certain attitude toward this content, and so presents a definite argument.

The weaknesses of this type of criticism are obvious: it tends to judge the work of art only on the basis of its message, and so neglects the formal, expressive, and structural features of art. The critics of this general caste are of more interest to the historian of ideas than to the aesthetician, and the schools need little detailed consideration from the artist's frame of reference. They have contributed greatly to intellectual history; but they have contributed very little to criticism, because they have not been interested in criticism as a process and profession, but only as a means to an end.

In conclusion, it should be emphasized again that all criticism has its basis in the simple statement, "I like that". That is, criticism depends upon the antecedent discovery of value. Hence, in the first place, there will be as many legitimate schools of critics as there are types of value to be found in literature: values of form, of meaning, of emotional effect, and of moral influence. Again, the critic is mainly concerned to discover and promote the value that he has discovered; which means, that he analyzes art in order to improve its quality. And it is in pursuit of this quite simple and very understandable goal that there emerge all of the refinements and distinctions that we have already discussed. —I.J.

**litharge** (Fr.). A form of lead monoxide, combined wtih various colors and used as painting media. See also mitsudaso.

**lithography.** See PRINTS AND PRINT PROCESSES.

**lithophone.** As a white pigment, this has had a very small use in the fine arts, though it is common in commercial paints. It is comparatively recent in origin, having been first produced and patented in England in about 1874. Commercially it is a co-precipitate of zinc and barium salts which produce a mixture of zinc sulphide and barium sulphate. This precipitate is commonly calcined before it is ground as a pigment. It is frequently used in connection with the cadmium sulphides as an extender and to a limited extent with other intensely colored pigments. —G.L.S.

**lithotint.** See PRINTS AND PRINT PROCESSES.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**Lithuanian art.** Attempts to study the development of Lituanian art meet with tremendous difficulties in view of the political and cultural changes that have marked the history of the people. The Lithuanians were among the last peoples of the eastern Baltic area to be definitely Christianized and by that time they had already created a powerful state with important castles on the East Baltic pattern in Trakai and other centers. There is a rich peasant art and among the most striking examples of this are the ornate crucifixes scattered throughout the country and which contain motifs drawn from pagan times adapted to their present purpose in a truly national manner and spirit.

Later part of the royal family, e.g. the descendants of Gediminas, came into contact with the White Russians and became Orthodox. White Russian became then the official language of the state and later when the pagan Jagiello was baptized in the Roman Catholic Church and married Queen Jadviga of Poland in 1386, Polish influence and culture was extended into Jagiello's capital of Vilnius (Wilno, Vilna). The higher artistic genius of Lithuania flowered in this capital with its superb brick Gothic churches (e.g. St. Anne), and later its baroque and classical monuments. These are claimed by both the Poles and the Lithuanians in view of the complicated way in which the two elements were united in the Polish Republic. Later came the Russian period and for the greater part of the 19th cent. Lithuania felt sterner methods of repression than did any of her neighbors.

The modern Lithuanian art, therefore, based on a revival of the peasant traditions as they have been handed down, began only at the ending of the 19th cent. and has followed the trends of modern times. Among the outstanding artists were K. Cviurlionis (1875-1914), a distinguished painter and musician who had been educated in St. Petersburg and who became one of the first to attempt a new national art; Antanas Zemaitis a painter of poetic delicacy; and the sculptor Petras Rimsa.

The period of liberation as elsewhere released the Lithuanian talents and a large number of new artists appeared. Yet the fact that the traditional capital of old Lithuania, Vilnius, remained in the hands of Poland, served to prevent the closest possible contact with the monuments of the past claimed by the Lithuanians; the question of the capital occupied an excessive part of Lithuanian energy. A great deal of work was done in the modernizing of the temporary capital of Kaunas and in architecture there was being developed a modernistic type based on the local needs. Nevertheless the coming of World War II and the difficulties caused by the Soviet and then the German occupation of the country disrupted most of the definite programs of work and has thrown the burden of maintaining the traditions on the Lithuanian groups abroad, esp. in the U.S.A. See E. J. Harrison, *Lithuania Past and Present,* 1922; W. St. Vidunas, *La Lithuanie dans le passé et dans le présent.*

—C.A.M.

**little magazine.** The journal of a coterie for the expression and propagation of doctrines looking to the reform of art and society. In England *The Yellow Book* (1894-7) and *The Savoy* (1896) enunciated an art-for-art's-sake theory in opposition to the prevailing Victorian standards of taste and morality. The *Chapbook* (1894-8) of Chicago for a time expressed similar *fin de siecle* opinions. Not until *Poetry* (1912- ) founded by Harriet Monroe in Chicago, *The Masses* (1911-7) edited by Max Eastman and Floyd Dell in New York, and *The Little Review* (1914-29) edited by Margaret Anderson and Jane Heap in Chicago, New York, and Paris arrived on the scene were there U. S. magazines effective in supporting experimentation and revolt. *The Masses,* which was discontinued in 1917 because its editors and some contributors were tried for treason and which continued as *The Liberator* (1918-24) edited by Robert Minor and as the monthly *New Masses* (1926-1934) edited first by Max Eastman and later by Michael Gold and then by Joseph Freeman, was the first of the little magazines in America to support social as well as literary experimentation. The weekly *New Masses* (1934- ) is said to be controlled by the Communist Party of the U. S. Another early advance guard magazine was *Blast* (1914-5) edited by Ezra Pound and Wyndham Lewis in London. *The Seven Arts* (1916-7) edited by James Oppenheim, Waldo Frank, and others in New York was discontinued because its patron objected to the magazine's opposition to World War I. It published important essays by Waldo Frank, Randolph Bourne, etc., *S4N* (1919-25) edited by Norman Fitts in Northampton, Mass., and New Haven, Conn., and *The Freeman* (1920-4) edited by Frances Neilson and Alfred Jay Nock in New York, contributed to the revolt which was to characterize the 20's. The latter was revived as *The New Freeman* (1930-2) to compete

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

with the *New Masses*, both of which were housed in offices at 112 E. 19th St., N. Y. C. The most august of the advance guard magazines was *The Dial* founded in New York as a monthly after an earlier career as a weekly in Chicago (1920-9) and edited first by Scofield Thayer (1920-5) and later by Marianne Moore (1925-9). There were other little magazines to swell the list: *Broom* (1921-4) edited by Harold Loeb, Alfred Kreymborg, Malcolm Crowley, and Slater Brown and published in Rome, Berlin, New York consecutively. *Contact* (1921) edited by Robert McAlmon and William Carlos Williams in Paris for five monthly issues and resumed in New York (1932) for four quarterly issues under the editorship of William Carlos Williams. Norman Macleod edited another number which was not issued by Martin Kamin, the magazine's publisher. The first little magazine to be published in the South was *The Double Dealer* (1921-6). It was edited by Julius Weis Friend and Basil Thompson in New Orleans. The next was *The Fugitive* (1922-5) edited by John Crowe Ransom, Donald Davidson, Allen Tate, and others in Nashville. Another important publication of the twenties was *Secession* (1922-4) edited by Gorham B. Munson, Kenneth Burke, and Matthew Josephson and published successively in Vienna, Berlin, Reutte (Tirol), and New York. The two most important little magazines edited by Americans in Europe were *This Quarter* (1925-6 under editorship of E. Walsh and Ethel Moorhead in Milan, Italy, and Cannes, France; 1929-34 under editorship of Edward Titus in Paris) and *Transition* (1927-36) edited by Eugene Jolas and published monthly in Paris (1927-8) and quarterly (1928-30). Discontinued in 1930. Resumed publication as a quarterly (1932-6) published by N. V. Servire in The Hague, Holland. Several issues in New York (1936). Discontinued. The magazine to continue from where *The Dial* left off was *The Hound & Horn* (1927-34) edited by Lincoln Kirstein primarily and published first in Cambridge, Mass., and later in New York. Ezra Pound contributes another magazine as the editor of *The Exile* (1927-8), which was published for four issues by Pascal Covici in Chicago. Surrealism was first given group expression in the U. S. A. by *Blues* (1929-33) edited by Charles Henri Ford first in Columbus, Miss., and later in New York. In competition with the Southern Agrarians (Allen Tate, John Crowe Ransom, etc.), Yvor Winters founded *The Gyroscope* (1929-31) and published it from Palo Alto, Calif. The bi-lingual (French and English texts) *Tambour* (1929-32) was edited by Harold Salemson and published in Paris. The most important advance guard magazine of the 30's to be published in America was *Pagany* (1930-3) edited by Richard Johns, first in Boston and later in New York. One of the most important advance guard critical journals was *The Symposium* (1930-4) edited by James Burnham and Philip E. Wheelwright in New York. Social and literary revolt are combined with internationalism in *Front* (1930-2) which attempted to present "the complex literary countenance of a world generation". It was a tri-lingual publication with English, French, and German texts and was composed of Soviet Russian (editor: FOSP, Moscow), Asiatic (editor: Masaki Ikedo, Tokyo), Latin American (editor: Xavier Abril, Lima, Peru), American (editor: Norman Macleod, New York), and European (editor: Sonja Prins, Amsterdam) sections. The two most important editors were Sonja Prins, who organized the European and Soviet sections, and Norman Macleod, who organized the American, Latin American, and Asiatic sections. Published by N. V. Servire, The Hague, Holland. Discontinued in favor of *International Literature* (1928— ) published in Moscow in separate Chinese, English, German, French, and Russian editions. Another tri-lingual advance guard review was *The Morada* (1930-32) published first in Albuquerque, N. M., and later in Cagnes, s/mer, France, by Norman Macleod and Donal McKenzie. The first little magazine (other than *New Masses*) to go Communist was *The Left* (1931-2) edited by George Redfield, Jay Du Von, and others in Davenport, Iowa. An International Note Book of the Arts was the sub-title of *The New Review* (1931-2) edited by Samuel Putnam in Paris. *The Partisan Review* (1935- ) was first published as the official organ of the New York John Reed Club which belonged to the American section of the International Union of Revolutionary Writers and was edited by Alan Calmer, Jack Conroy, Ben Field, William Phillips, and Philip Rahv. The last two named in 1937 took the magazine with them when they broke with the leftist group above mentioned and continued its publication together with Clement Greenberg, Dwight Macdonald, and George L. K. Morris, who supported the magazine financially. *The Partisan Review* is now an independent left literary little magazine which neither supports World

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

War II nor opposes it. *The Southern Review* (1935-42) was edited by Cleanth Brooks, Robert Penn Warren, etc., and published at Baton Rouge, La. *Accent* (1940- ) is a conservative little magazine published in Urbana, Ill. *View* (1940- ) edited by Charles Henri Ford in New York and *VVV* (New York) reflect the influence of André Breton and French Surrealism, which has come to New York to escape annihilation at the hands of the Nazis. The American Surrealists maintain close communication with their colleagues in South American who are said to constitute one of the main literary developments south of the Panama Canal. —N.M.

**lituus.** See MUSICAL INSTRUMENTS.

**Liuthar group, the.** See Carolingian art; See Ottonian art.

**lizard.** See SYMBOLISM IN FAR EASTERN ART.

**loan exhibition.** See exhibition.

**local color.** A form of fiction popularized in the U.S.A. by Bret Harte in 1868, although stories of this type had been written as early as 1834 by Harriet Beecher Stowe and A. B. Longstreet. Emphasis is placed upon unique geographic or atmospheric effects; upon odd, whimsical, or unique characters who speak in dialect; and upon local customs, dress, and superstitions. Harte's stories, set in the California Gold Rush of 1849, pictured against the red hills in dry or snowy weather a set of moral reprobates—gamblers, saloon keepers, and prostitutes—who revealed heroic, saintlike qualities in an emergency. By combining certain narrative techniques of Dickens, Irving, and Hawthorne, Harte gave surge as well as depth to his narratives; and by employing the comic devices of tell-tale (q.v.) humor, he interested a vast audience. Writers in other areas immediately saw the possibilities in their local material, so that by 1910 almost every region in the U. S. was pictured. The other most memorable writers with their localities are: Sarah O. Jewett, Maine; Mary E. W. Freeman, Mass.; Alice Brown, N. H.; Rose T. Cooke, Conn.; E. N. Westcott, Upper N. Y. State; Helen R. Martin and Elsie Singmaster, Penna. Deitsch; Margaret Deland, Western Penna.; T. N. Page, Va.; J. L. Allen, Ky.; Mary N. Murfree, Tenn.; C. W. Chestnutt, N. C.; J. C. Harris and H. S. Edwards, Ca.; Mary H. Catherwood, Ohio; E. F. Eggleston, Ind.; Constance F. Woolson, Mich.; Hamlin Garland and Zona Gale, Wis.; Alice French, Ark.; G. W. Cable, Crace E. King, Ruth M. Stuart, and Kate Chopin, La.; T. A. Janvier and C. F. Lummis, N. M.; P. V. Mighels, Nev.; Mary H. Foote, Idaho; and Frank Norris, San Francisco's Chinatown. Under the impact of the realistic theories of fiction introduced from Europe, local color merged into the New Regionalism (q.v.) or became the sublimated basis for universal studies like those of Willa Cather and Sinclair Lewis. See H. R. Warfel and G. H. Orians, *Am. Local-Color Stories,* 1941. —H.R.W.

**locus.** See PERSPECTIVE.

**log.** A bulky piece of timber cut down and cleared of branches; usually more than five inches in diameter.

**lohan** (Ch.). Buddhist saint.

**Loire, school of.** See FRENCH ART.

**Lokeśvara.** The form of Avalokiteśvara found in Cambodia, and elsewhere. He is the god of compassion and power.

**lokweave.** Type of carpeting particularly adaptable to practical use. This fabric requires no binding and due to the fact that it can be cut in any direction without raveling, it is excellent for use in odd-size rooms. Also as this fabric permits the joining of any number of pieces together through the application of a patented sealer on the back, no visible seams spoil the appearance of the completed installation. Therefore, any pattern or design can be executed in any desired color scheme. One of the other advantages of this type of carpeting is that if any damage is done to the rug, such as a bad stain or burn, etc. the damaged spot may be cut out and a new piece inserted and sealed into place, thus protecting the life of the carpet. .—B.E.J.

**Lombard architecture.** The style of medieval building in the north-Italian region which took its name from an invading tribe of German barbarians, but developed its architecture on Roman traditions under strong Byzantine influence received through Ravenna. King Rotharis (636-52) set up a code of the Comacine masters (q.v.) which has been widely interpreted as the basis of masons' guilds centered at Como, though the word probably means co-workers on the scaffold (*macigno*). The simple early Lombard structures are built

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

of brick or of small stones resembling bricks, with some vaulting, and decorations of pilaster strips and corbel tables. The Lombard style spread to Dalmatia, Southern France, Catalonia, and the Rhineland in the course of the 9th, 10th, and 11th cents. Outside Italy it was superseded by regional schools of Romanesque architecture after 1100. By that time notable structures in developed Lombard Romanesque were building. Square bays with rubble groin vaulting on ribs supported by grouped shafting were then in use, and it has been thought that influential Lombard churchmen going to Normandy and England were responsible for the appearance there of these features, which soon brought about the development of Gothic architecture. See Porter, A. K., *Lombard Architecture,* 1915-17: Puig i Cadafalch, *La géographie et les origines du premier Art roman,* 1935; Clapham, A. W., *Romanesque Architecture in Western Europe,* 1936. —K.J.C.

**Lombard porch.** A porch projecting from a church portal and supported by disengaged columns resting on bodies either of lions or of griffins. Introduced into Lombardy in the beginning of the 12th cent. —R.B.

**long.** See neumes.

**longa.** See NOTATION.

**longa imperfecta.** See NOTATION.

**longa perfecta.** See NOTATION.

**long bench.** See FURNITURE.

**long room.** See MESOPOTAMIAN ART.

**long scroll.** See CHINESE ARTS.

**loom, hand weaving.** A mechanical apparatus upon which the rug is woven, consisting of a heavy wooden framework over which the threads that are to be the foundation of the rug are stretched. —B.E.J.

**looseness.** As applied to literature, this term indicates a lack of internal connection between the various elements of the work. Looseness is the condition that holds when the passage from one part of the work to another is weak and unstable; it has the effect of isolating the various segments of the work, and so destroys artistic unity. —I.J.

**Lopburi, school of.** See SOUTHEASTERN ASIATIC ART.

**lost wax method.** See cire-perdue.

**lotus.** A conventionalized ornament based on a water lily of Egypt or Mesopotamia, a symmetrical unit either (1) in bud form, a long thin pointed bud, or (2) in blossom form, a petal curving out toward the top on each side of a central pointed member; widely used in ancient Egypt, Mesopotamia, and Greece. See SYMBOLISM IN FAR EASTERN ART. —L.T.S.

**lotus and palmette.** Also called lotus and palmette chain, or anthemion; a continuous classical ornament in which the units are alternately a lotus blossom and a palmette, and are connected at the bottom by a double curved or S-scroll; widely used on Greek pottery and in Greek and Roman architecture. —L.T.S.

**lotus throne.** Pedestal designed with lotus petals surrounding a lotus pod motive, on which, in pictorial and sculptural art, the Buddha is usually seated.

**loud, loudness.** See ACOUSTICS.

**Louis Quatorze (XIV) style.** See FURNITURE.

**Louis Quinze (XV) style.** See FURNITURE.

**Louis Seize (XVI) style.** See FURNITURE.

**Louvain school.** A school of 15th cent. Flemish artists at Louvain. It was here that Dierick Bouts developed his style of landscape which influenced the school of Cologne. —R.L.W.

**low relief.** See relief; relief sculpture.

**low warp loom.** A loom with the warp in a horizontal position. The worker leans over such a loom while weaving as if writing at a table.

**Lowestoft ware.** See CERAMICS II.

**Loyal subjects.** See ORIENTAL MUSIC.

**Lucca della Robbia ware.** See CERAMICS II.

**Luhrs.** See PREHISTORIC ART.

**Lumia** (also called mobile color, color music, the art of light). An eighth fine art form in which light is used as a direct and independent medium for aesthetic expression. The aesthetic treatment of mobile form and color in apparent space.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

A lumia composition is a silent visual sequence performed on a white screen by means of a light projection instrument controlled from a console (see clavilux). A special notation system is used by composer and performer (lumianist.)

The basic factors of lumia have been set forth by Thomas Wilfred in the following frame of reference:

| | | |
|---|---|---|
| FORM | POSITION<br>VOLUME<br>OUTLINE<br>CHARACTER<br>(Texture, Opacity) | The periodic change within any one or any combination of the twelve sub-factors constitutes RHYTHM. |
| MOTION | ORBIT<br>TEMPO<br>CYCLE<br>(Recurrence)<br>FIELD* | |
| COLOR | HUE<br>CHROMA<br>VALUE<br>INTENSITY** | |

*FIELD is that area of imaginary space visible to the spectator. A composition may either be completely contained within this area (single field)—or much of the sequence may, by inference, develop without and be visible only as orbit and field coincide (double field).

**In lumia it has been found expedient to add intensity to hue, chroma and value since a given combination of the three latter may remain relatively unchanged while being moved into a higher intensity dimension by means of added candlepower from the light source.

Lumia, being in its purest form a space-time, art, color is the only dispensable basic factor. Experimental programs of black and white compositions have been successfully played by Thomas Wilfred in the recital hall of the Art Institute of Light in New York City.

The lumia artist must first of all create a perfect illusion of depth. The flat white screen must become a window, opening on infinite space in which form, motion and color interweave. A composition may begin with a tiny sphere of pale blue in the far distance, approaching the spectator through rising clouds of green tendrils and opening up into a flaming climax of intense warm colors. This cycle may be repeated with variations until the composition ends with the sphere receding through the undulating curtains of green tendrils until it vanishes in the distance.

Lumia composition ranges from the purely abstract to the stark representational—from the majestic to the grotesque. Among the pioneer artist Thomas Wilfred's 132 compositions we find such titles as *Study in Rising Forms,* Op. 75; *Rhythm in Steel,* Op. 71; *Counterpoint in Space,* Op. 96; *Triangular Etude,* Op. 39 and *Chorus,* Op. 69.

Lumia has been used in conjunction with music and drama (see *Encyclopedia Britannica,* 14th Ed. Vol. 21, pp. 189-190), the dance and architecture (projected mobile murals, interior and exterior decoration with light).

The art form is still in its infancy and its instruments primitive but it opened up a new field of great importance in aesthetics. Lumia has also been applied with success in psychotherapy through a series of special arrangements built at the Art Institute of Light.

—T.W.

**luminance.** See COLOR.

**luminescent bodies.** See COLOR.

**luminism.** See impressionism.

**luminosity.** See COLOR.

**luminous emittance.** See COLOR.

**luminous (visual) energy.** See COLOR.

**lunar cult.** See PRIMITIVE ART.

**lung** (Ch.). Dragon. See SYMBOLISM IN FAR EASTERN ART.

**lung** (Ch.). Jade disc, or split disc, with circular perforation in center, and with dragon heads *en face;* symbol of fertile rain and therefore used ritually in prayers for rain.

—J.A.M.

**Lung-ch'üan yao** (Ch.). Chinese ceramic ware with either a porcelain or pottery base and the gray-green glaze popularly known in the occident as celadon (q.v.).

**lung-mên.** See SYMBOLISM IN FAR EASTERN ART.

**Lungmen caves.** See CHINESE ARTS.

**lur.** An ancient Scandinavian trumpet or horn. See MUSICAL INSTRUMENTS.

**lute.** See MUSICAL INSTRUMENTS.

**lute style.** See gallant style.

**lutschism** (Ger.). See rayonism.

**Lydian mode.** See idiom A (2); scales and modes.

**lyra, l. da braccia, l. da gamba, l. viol, lyre.** See MUSICAL INSTRUMENTS.

**lyric oratorio.** See ORATORIO.

**lyric poetry.** See POETRY.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

# M

**machine art,** exactly speaking, is distinguishable from handicraft, though it is clear that a sharp separation cannot be made. Perhaps the dividing line should be drawn where the motive power is or is not human, rather than where the degree of complication of the tool used suggests a mechanical emphasis as opposed to a human one. As commonly understood, however, the term, *machine art,* applies to the articles produced by mass production methods, a process developed since the Industrial Revolution. With this connotation the term separates articles mechanically produced, which make claims to artistic form, from those which do not.

Historically speaking, the interest in machine art followed that aroused by the arts and crafts movement (q.v.) in the late 19th cent., as a reaction to that movement's total condemnation of the machine when used to create art.

In the early stages of machine art various decorative formulas were followed, called now art nouveau, now Viennese Secession, art moderne, and latterly, streamlining—all attempting to use the machine, but denying its total validity. Later, technical problems as solved by engineers tended to dominate individuality in artistic creations which stressed utility and functionalism in design. Following the First World War, a reaction set in which emphasized the originality of the artist's creation. In the 20's and 30's a counter-reaction flourished, this time back to techniques derivative from new materials and processes and uses, as illustrated by tubular metal and plywood furniture. As the 1940's pass and a post-war world is envisaged, it appears that the machine may in time be humanized, and that the forms which man designs through its instrumentality will develop their own range of aesthetic values. The machine will not be forced in that event to imitate handicrafts, but it will be so controlled that the product will express both the creating mind of the artist and the guiding hand of the operator, as well as the process, the material, and the purpose which the object will serve. That a machine aesthetic is gathering force and clarity has been indicated by the Machine Art Exhibition held at the Museum of Modern Art, New York City, in 1934, where Plato and St. Thomas Aquinas were summoned to endorse the beauty of machine forms, and where industrial units, household and office equipment, kitchenware, home furnishings, and accessories, scientific instruments and laboratory glass and porcelain were expertly displayed to reveal unsuspected beauty of geometry and rhythm, of technique and material, of intricacy and simplicity. Pertinent relationships have also been pointed out between the beauty of machine art and that of natural forms, between machine aesthetic and that of abstract art, and between machine art and the new awareness of time-space which tends to color our sociological thinking, as it encompasses housing, transportation, and regional planning.

In America the former leaders of the Bauhaus, Dessau, Germany, as well as Norman Bel Geddes, Walter Dorwin Teague, Harold van Doren, Alvar Aalto from Finland, and many of the most distinguished modern architects are leaders among designers of Machine Art, though there is hardly a craft which has not its forward-looking advocates who are helping to hasten the day when even the peculiar beauty of machine art will no longer be exploited, but when the human being, with his manual powers extended by the machine he has designed will produce objects, both those made

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

to order and those completed on a moving belt, of human significance. Lewis Mumford in *Technics and Civilization* has written a suggestive introduction to the understanding of such an environment.

From a world of mass production and objects composed of standardized units only a representative series of examples can be suggested here. Greenbelt towns, sponsored by the American government, great Federal engineering and regional developments such as the Tennessee Valley Project, the motor parkways of Westchester County, New York, the concrete bridges of Robert Maillart in Switzerland, the Johnson Wax Company office, Racine, Wisconsin, with mushroom supports and imaginative lighting created by Frank Lloyd Wright, make quite clear that the lesson of motor car, and steamboat, and airplane have been learned, as well as that of the Parthenon and of the human body and arrow-heads.

On a smaller scale such details as the metal doors of vaults at the Philadelphia Savings Fund Society Building by Howe and Lescaze, the standardized telephones of the Bell System, the basic equipment of the transcontinental flyers, the revolutionary uses of glass used to relate interiors to environments, and the transformation seen in the design of every article used in domestic furnishing and consumption from stove to lighting fixture to textile to easy chair are too numerous and too obvious to mention further. The machine is clearly being accepted and allowed to create its own type of beauty as the values of metal and wood and plastics are sought and found.

But more amazing, perhaps, than the novelty seen in new forms occasioned by new practices and needs, and the exploitation of new materials, is the revolution to be seen in the traditional art forms. Siqueiros paints with Duco-spray, photography is developing a mural phase, pre-cast concrete blocks are used for architectural decoration, machine-made glass is produced in bendable form for structural use and in mass production rivals the beauty of hand-made products, and premiated furniture designs, resulting from understanding raw materials, new techniques, and the human body, are turned over to mass production as soon as prizes are announced. Even the province of typography and book-making is being re-explored and type-faces expressive of modern ideas and new formats for a visual-minded and hurried reader are making cautious advances to the machine, while the late Grant Wood admittedly painted pictures with the demands of magazine reproduction in mind. Thus does a democracy move to the mastery of the machine.

For the theories of machine art forms, cf. J. L. Martin, etc., editors, *Circle,* 1937; *Machine Art,* Museum of Modern Art, New York, 1934; S. Giedion, *Time, Space, and Architecture,* 1941; L. Moholy-Nagy, *The New Vision,* 1938; L. Mumford, *Technics and Civilization,* 1934. For historical backgrounds, cf. E. A. Park, *New Backgrounds for a New Age,* 1927; L. F. Day, *Of William Morris and His Work,* 1899; N. Pevsner, *Pioneers of the Modern Movement,* 1936. For architecture and machine art, cf. F. L. Wright, *Modern Architecture,* 1931; W. Gropius, *The New Architecture,* 1935; Le Corbusier, *L'art decoratif d'aujourdhui.* For interiors, cf. P. T. Frankl, *Form and Reform,* 1930, and *New Dimensions,* 1928; J. Aronson, *Furniture and Decoration,* 1941. For types of machine art, cf. *Organic Design,* Museum of Modern Art, New York, 1941; S. and M. Cheney, *Art and the Machine,* 1936; N. Teague, *Design This Day,* 1940; Harold van Doren, *Industrial Design,* 1940. Cf. also, K. Blossfeldt, *Art Forms in Nature,* and D. E. Mansberger and C. W. Pepper, *Plastics: Problems and Processes,* 1938. —W.S.R.

**madder.** As one of the lake or dye pigments, the madder or madder lake was probably as well known as any of the red coloring materials used by painters since classical times. It is usually considered to be the *rubia* mentioned by Pliny, and specimens of it have been found on paintings of Egyptian and Greco-Roman times. It is a natural dye extracted from the root of the *Rubia Tinctorium.* Until recently this was cultivated exclusively in Europe and Asia Minor. Synthetic dyes such as alizarin have largely displaced it. —G.L.S.

**madras.** A cotton fabric made with leno weave.

**madrasa.** See ISLAMIC ART.

**madrigal** (matricale). A vocal, unaccompanied composition, generally in imitative counterpoint in from 3 to 8 parts. The madrigal is closely allied to the motet. It differs from the glee in that it is sung by a chorus,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

while the glee is intended for solo voices. See MEDIEVAL MUSIC.

**magatama** (Jap.). A bead or pendant, shaped like a comma. Its significance is lost in antiquity.

**Magdalenian art.** See PREHISTORIC ART.

**Magen Avoth mode.** See JEWISH MUSIC.

**magenta.** The name given to a brilliant reddish purple color, this is also the name of a particular dye synthetically made and belonging to the triphenylmethane group. It was first prepared in the middle of the 19th cent. and, although a fugitive material, is used still as a water color. —G.L.S.

**magic realism.** See new objectivity.

**mahlstick.** Held in the palette hand of the painter and used as a rest for his painting hand, especially in the execution of fine work, is the mahlstick. Evidence of its use goes back to the 16th cent. where it is seen in representations of painters' studios, particularly of St. Luke. It is a light rod of wood, ordinarily with a soft leather-covered ball at one end. This ball is made to rest against the painting, if necessary, or against a part of the easel. Commercially made mahlsticks are of hardwood or bamboo jointed to give them a total length of about four feet. The name, rest stick, is also applied to them. —G.L.S.

**maitre de ballet** (Fr. ballet-master). In the original 17th cent. meaning, the ballet-master trained the company, was responsible for its schooling as well as its performance on the stage. Today, this work is divided into the teacher's, the rehearsalist's, and the choreographer's, while the choreographer is usually understood as *maitre de ballet.* —L.K.

**majolica, maiolica ware.** Lustrous, colorful, opaque glazed pottery. See CERAMICS I, II; faïence ware.

**major.** See key.

**major interval.** See interval.

**major mode.** See scales and modes.

**major scale.** See NOTATION.

**majuscule.** Capital letter. See writing.

**makara** (Skr.). A crocodile-like mythical monster with fish tail; often used decoratively in the sculpture of India and the Indonesian countries.

**make-up.** See COSTUME ART.

**maki-e** (Jap.). Lacquerware (q.v.), in relief.

**makimono** (Jap.). Literally "rolled thing". A painting mounted so as to be rolled or unrolled horizontally.

**makkinro** (Jap.). An ancient lacquer technique in which a design in coarse gold dust is laid on a ground of black lacquer, then covered with black lacquer and polished through. —J.A.M.

**malachite.** Closely associated with the blue known as azurite, malachite is a similar mineral, a basic copper carbonate. It is green in color and has sometimes been given the name, mountain green. The mineral is prepared as a pigment by selection, grinding, and sieving. Formerly much used in Europe through the Middle Ages and the Renaissance, it is now no longer prepared by artists' colormen. It appears still with azurite as a pigment used in the Far East, and has evidently been in the palette of artists in that region since Han times. —G.L.S.

**Malaga ware.** See CERAMICS II.

**malagueña.** A national Spanish couple dance in the sequidilla tradition belonging to the classic Iberian group. The dance is partly mimetic in character, using flirtation as its theme. The woman carries a fan and the man a cape, which he flourishes in movements suggestive of bull-fighting. The movement is fast with intricate, rapid footwork, punctuated by abrupt pauses. In form, the dance consists of three sections; the promenade, the pantomime, and the dance proper. —J.G.

**mallet of daikoku.** See SYMBOLISM IN FAR EASTERN ART.

**Mamluk art.** See ISLAMIC ART.

**manaia** (Maori). The squat human figure, a recurrent and basic motif in Maori carving (q.v.).

**mandala** (Skr.). A temple painting showing a portion or all of a pantheon with mystic symbols often arranged geometrically. See INDIAN ART; stupa.

**mandapa.** See INDIAN ART.

**mandara** (Jap.). See mandala.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**mandarin duck.** See SYMBOLISM IN FAR EASTERN ART.

**mandolin, mandoline.** See MUSICAL INSTRUMENTS.

**mandorla.** See aureole and mandorla.

**mandriale.** See madrigal.

**manfukh** (Ar. swollen) arch. Horseshoe arch. See ISLAMIC ART.

**mang.** See SYMBOLISM IN FAR EASTERN ART.

**manga** (Jap.). Sketches, generally assembled in book form; cartoons.

**manganese pigments.** The blue and violet colors from the manganese metal are of quite modern origin. Manganese violet, a manganese ammonium phosphate, first appeared on the market in 1890. A synthetic pigment, this is inorganic and is quite permanent to light and heat. It is decomposed by strong acids or by alkalis. Its color is not extremely brilliant and its hiding power is weak. Manganese blue is still more recent in origin and is first mentioned in the patent literature in about 1935. It is somewhat more complex, being essentially a barium manganate fixed on a barium sulphate base. Chemically, it is inert and is not affected by heat or by strong acids or alkalis. Like the violet color, it is weak in tinting strength and in hiding power. —G.L.S.

**Manieren.** *Mus.* German term for ornament. Philipp Emanuel Bach devotes in his famous treatise *Versuch über die wahre Art das Clavier zu spielen* nine chapters to Manieren, offering a detailed study of ornaments. He specifies the following types: I. Manieren in General; II. On Appogiature; III. On Shakes; IV. The Turn; V. Mordents; VI. The Anschlag; VII. The Schleifer; VIII. The Schneller; IX. On the Ornamentation of the Fermata. —F.D.

**manikin.** Evidently older in the history of the art than the lay figure, the manikin is similar. As an adjustable model, it is made to imitate the human figure and is used particularly in the representation of costume and drapery. In it there is no attempt to conceal the mechanical articulation of joints and there is no attempt to imitate superficial forms. The commercially made manikins are usually of wood and the size ranges from about a foot in height to approximately life size. Figures of this type were known as early as the 16th cent. in artists' studios and may have been part of the equipment of such rooms at earlier dates. —G.L.S.

**manila.** *Book.* A paper and a card. Made from manila hemp in the best qualities, but imitated with other materials.

**manji** (Jap.). Swastika.

**Mannerism** as a universal phenomenon occurs whenever in any art the exhibition of formal dexterity is dominant at the expense of the rendition of expressive or representative content. Its appearance can accordingly be due to the exhaustion either of the creative impulse or of the ideas underlying creative activity.

As the name of a style, the word is applied to most European art between 1520, the end of the High Renaissance outside of Venice and 1600, the beginning of the baroque, its applicability being coextensive with that of the term "Late Renaissance". The style of Mannerism is a "manneristic phenomenon", since (1) it relies on ready-made formulae with disregard for their functional context; since (2) it lacks the naïveté of an art aware of tasks ahead; since (3) it puts a premium on ingenuity in the planning of involved compositions and of abstruse literary programs.

Mannerism is an anti-classical style in that it sets itself against the progressive rationality of the Renaissance. In some cases (Michelangelo, Pontormo) this is due to religious desires and may then involve a resumption of artistic forms of the Middle Ages, just as some phases of Mannerist theory of art have a mystical and medieval flavour (Lomazzo, Zuccari). Usually, however, the dissonances of Mannerism are no more than free variations upon motives of the High Renaissance, which remain the basis of the new art: witness the adherence even in the most anti-classical architecture to Vitruvius' orders of columns. Mannerism, then, presupposes classicism as any deviation or irregularity presupposes a rule. It indulges in deviations from the classical style, because it regards it as the embodiment not of a valid view of the world, but only of a set of prescriptions which the artist feels at liberty to accept or to reject.

Typical traits of the Mannerist style are (1) the general instability of composition, which in painting is often without any aesthetic center and in architecture sometimes

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

gives the impression of the upper parts being overweight; (2) the denial or exaggerated assertion of space, which is either compressed into a narrow frontal zone with disregard for the real distance of the figures from the picture plain or lengthened into a bottomless chasm. In both cases the space composition is unstable, in the first also paradoxical. (3) The ambiguous interpretation or outright perversion of functional relationships. In architecture this leads to such paradoxes as the incorporation of columns into the walls which they are to support, or the treatment of brackets as if they were suspended (vestibule of Bibliotheca Laurentiana). In painting, the divorce of form and function is expressed by the emptiness of gestures which instead of arising from a situation, are merely superficially adapted to it. Frequently several conflicting interpretations of the same group of forms are simultaneously forced upon the spectator, who will be both attracted and repelled by such duplicity. Mannerism is therefore (4) the style of interlocking forms and of conflict without issue. Therein lies its essential futility.

Escape from this impasse was sought by means of the following devices: (1) the reversion from structural form to ornament. In architecture this implied in some cases the annihilation of all specially architectonic content (P. Ligoria). (2) The reversion from consciously elaborated form to the pathological forms of the "subconscious": witness the frequency of double images (q.v.) or the interpretation of ornamental details as threatening physiognomies and masks. (3) The reversion from artificial form of any kind to the crude unformed matter of inorganic nature. Witness the introduction of artificial grottos and the use of uncut rock in the midst of highly elaborate architecture (Giulio Romano). (4) The reversion from unresolved conflict to rigidity: witness the coldness of classicistic form and the absence of expressive content in the work of the latest Mannerists (Cavalier' d' Arpino.). Witness also the iciness of Mannerist portraiture (Bronzino) which instead of rendering living human beings renders only their masks.

The rise of a Mannerism in the 16th cent. is due to the interplay of two circumstances: (1) the incipient emancipation of art from medieval bondage as a result of the pride of artist in the achievements of the Renaissance; (2) the worthlessness of these achievements in the face of the new spiritual demands of the day (see counter reformation). As a result of this conflict the new formal mastery was deprived of its ideological justification and became pointless artistry. The ensuing spiritual confusion is expressed through images of unresolved contrast and often of oppression and anguish. See GERMAN ART. —R.B.

In dancing, a mannerism is a personal idiosyncratic accretion or emphasis on the corpus of the academic traditional vocabulary presupposed by every technician, which is the individual contribution of every dancer. —L.K.

**man of sorrow.** Late medieval devotional image (q.v.) representing Christ after his death, upright and suffering from the wounds inflicted during the Passion, frequently also exhibiting his injuries and thereby inviting the compassion of the beholder. —R.B.

**mansions.** See STAGESETTING; THEATRE.

**mantel.** The work, or facing, over a fireplace in front of the chimney. See INTERIOR ARCHITECTURE AND DECORATION.

**mantling.** See HERALDRY.

**Maori.** A Polynesian people living in New Zealand. For Maori art see OCEANIA, ARTS OF; Maori carving.

**Maori carving.** Few primitive peoples have such an individual form of art expression as the Maoris of New Zealand. An isolated geographic position and relatively rigorous climatic conditions tended to force the development of a local art style which was quite distinctive from that of other south sea island groups.

A careful survey of a map of the southern Pacific will show that the land of the Maoris is indeed at the very edge of the inhabited world. In spite of this, a fleet of Polynesian outrigger and double canoes carrying colonists from Hawaii crossed a broad expanse of the Pacific and settled in New Zealand a hundred years or so before Columbus dared to leave the shores of Europe.

For over three hundred years these people remained unmolested, developing an individual culture pattern and adapting themselves to their new environment. Among other things, the Maoris discovered that the fine-grained **totara wood** offered excellent material for carving. From the **greenstone**

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

(nephrite) which was found locally, they were able to fashion sharp cutting-tools which were as hard as common steel. With such materials at hand is it any wonder that the Maoris turned to wood carving as the means of preserving their traditional art forms? Being a rhythmic people with latent abilities they gradually attained a technical skill seldom reached by stone-age cultures.

Living in a country where practically no animals existed and where even the birds were relatively small and timorous the Maori carver lacked the fearsome models which so commonly inspired the primitive artist to create terrifying animistic forms. Instead the Maoris worked in a profuse decorative manner using few major motifs and filling background areas with abstract curvilinear patterns. Most of the carving was done in relief.

Of the larger motifs the most important were the squat human figure, the **manaia**, and the double spiral. These appeared most frequently and with the greatest variation both in treatment and size. Other large motifs such as the **marakihau**, the whale and the lizard were much more standardized and limited in their use.

Apart from the double spiral, the squat human figure motif seems to be basic in Maori carving. Unhampered by any desire for realism the trained **tohunga** adapted the human form to the rectangular plank which he carved. The head, being most important, was enlarged to fill the top part of the rectangle. The eyes, which were represented by disks of inlaid *paua* shell, were set under slanting brows. The nose was little more than a stylized "m" shaped unit. The mouth was greatly emphasized, with wide decorated lips and a tongue which protruded as a gesture of defiance. The body was greatly shortened and subordinated to the shoulder and hip joints which were usually expressed by large double spirals. The arms were little more than curving bands ending in three-fingered, claw-like hand designs. The feet were treated similarly to the hands being joined directly to the hip-spirals. Over most of the exposed surfaces were carved variations of notched, seed-like elements contained in parallel grooves.

While this squat human motif symbolized the story of the great ancestral heroes on the interior panels of the large community houses, at other times it seemed to serve as little more than decoration.

Another major motif which was just as important as the squat human figure and which indeed appears to be interchangeable with it was the sinuous grotesque form known as the *manaia*. This motif has a curving body surmounted by a bird-like head, which on closer inspection seems to be nothing more than the regular head-design split in half. This process of division is not uncommon in other Pacific arts, particularly those of the West-coast Canadian Indian. The body is an "s" curve which is grasped at the middle of the forward thrust by the large three-fingered hand motif.

A study of the taiaha, the canoe prow, the door lintel and particularly the exterior of the carved storehouse will show how both the squat human motif and the manaia design were variated and adapted to the shape of the area they had to fill. It will also be noted that in many places the figure disintegrated until the various members of the body became abstract units of decoration, complete in themselves.

The double spiral is not so easy to explain. Neither the Maori chiefs nor the scholars of Maori culture have reached any agreement upon its meaning. It appears most prominently on the canoe prows and on door lintels. Its very structure suggests that it does not originate from nature. This motif diminishes at times to small whorls of surface decoration.

Three creature motifs, the *marakihau*, the izard and the whale all resulted from environmental factors. As each of these designs were reserved for the decoration of a particular place they did not tend to develop as to either complexity of form or use, and may be considered as of minor importance.

The *marakihau* symbolized a human ancestor who had assumed the form of a legendary sea-monster. In appearance it was similar to the squat human figure except that the feet were replaced by a fish tail, the tongue was long and tubular, and the head showed two horn-like appendages. This design usually appeared on one or two of the carved panels of the large community houses.

The lizard, which was the most naturalistic motif of Maori art, was copied directly from nature. As in other aboriginal cultures it symbolized death and was used in the decoration of coffins.

The whale motif was carved with a fairly naturalistic body and tail but with the head represented by two interlocking curves. This design symbolized a period of plenty and was

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

most appropriately chosen to ornament the façade of the carved storehouse.

Unlike most primitive peoples the Maoris did not evolve different motifs or totem designs to signify the various tribes or clans. Instead, the same major motifs were used throughout the entire culture of the Maoris. The individuality of each district was displayed by the local treatment of these motifs and their particular arrangement. Thus, the placing and the emphasis of the spirals and squat human figure designs on a door lintel would intimate to the scholar where it was carved.

While it is true that the Maoris attempted to crystalize their history and mythology in their art, the very decorative and ornate profusion of the carving, plus an intense community pride suggests very strongly that there was still another underlying factor—the prestige element. Even though Maori carving is preponderately symbolic, nevertheless it is definitely used to express and increase the prestige of the community both in the eyes of the group and of their neighbors. See OCEANIA, ARTS OF; also *Maori Artistry,* W. Page Rowe, 1928; *Maori Carving,* Carter B. Storr, 1943; *The Maori As He Was,* Elsdon Best, 1934; *South Sea Folk,* Gilbert Archey, 1937. —C.B.S.

**maple.** See SYMBOLISM IN FAR EASTERN ART.

**maqsura** (Ar.). A fenced-off area in the *rivaq* (roofed arcade) of a mosque. See ISLAMIC ART.

**maraca.** See MUSICAL INSTRUMENTS.

**marae.** A sacred enclosure or place of worship of the Polynesians. See OCEANIA, ARTS OF.

**marakihau** (Maori). Sea-monster motif in Maori carving (q.v.).

**marbling.** *Book.* The process of imitating marble on paper, etc. Edges so treated are marble-edges; and papers are marbled endpapers, and so on. The man doing the work is a **marbler.** —H.E.S.

**marginal (district).** See CIVIC PLANNING.

**margins.** *Book.* The white borders around the type of a book page.

**marimba.** See MUSICAL INSTRUMENTS.

**marine painting.** A painting making use of seascapes or marine objects.

**marmorarii Romani.** See Cosmati work.

**marquetry.** Inlaid work, as in furniture.

**Mars.** See Ares.

**Mars pigments.** A range of colors from yellow to violet through orange and red have been made artificially by precipitating a mixture of a soluble iron salt and alum with an alkali like lime or potash. These are similar in a general way to the earth yellows and reds. They may be somewhat brighter in color and are rather more fine in grain than the natural products. —G.L.S.

**Maruyama school** (Jap.). School of painting depicting subjects of nature in a realistic style.

**marver.** See GLASS AND GLASS-MAKING.

**masjid.** (Ar.). A Mosque. See ISLAMIC ART.

**mask, masque.** See THEATRE; OPERA; STAGESETTING; COSTUME ART.

**Mass** (L. *Missa*). The ritual in celebration of the Eucharist or Lord's Supper. The Mass falls into two divisions, the Ordinary and the Proper. The former consists of unchanging texts: the Kyrie, Gloria, Credo, Sanctus and Benedictus, and Agnus Dei. The texts of the Proper, principally the Introit, Gradual, Allelulia or Tract, Offertory and Communion, change according to the commemoration of the season or saint. Apart from the original plainsong settings, little music has been composed for the Proper of the Mass. The Ordinary, on the other hand, because of its fixity and range in religious expression, became in the hands of great 15th and 16th cent. schools the most significant art-form of the period. See Liber Usualis for plainsong melodies. See requiem mass; MEDIEVAL MUSIC; for mass (small letter). See PSYCHOLOGY OF DRAWING AND PAINTING; also for Mass see P. Wagner, *Geschichte der Messe,* 1913. —V.A.

**massicot.** Derived from the mineral, lead, of which this is a monoxide, massicot has a clear yellow color. Traditionally, it is made by the gentle roasting of white lead at a temperature of about 300°C. Litharge is another

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

name given it, although that may be used to designate a pigment more orange in color. The yellow lead monoxide, massicot, undoubtedly had a common use with painters during the Middle Ages and the Renaissance, and there is evidence to show that it was known from predynastic times in Egypt.

—G.L.S.

**mastaba, mastabah.** A type of tomb, oblong with sloping sides and connected with a mummy chamber in the rock beneath; characteristic of the tomb masonry of the Old Kingdom in Egypt. See EGYPTIAN ART.

**masterpiece.** A term which can be traced back to the medieval custom of requiring a craftsman who applied to his guild for the title of "master" to present a specific piece of work as evidence of his skill. The word was later applied to anything that seemed worthy of a master-craftman; but as the guilds disintegrated and the competition between skilled workmen grew freer and more intense a demand developed for more superlatives and the term *masterpiece* was reserved for the finest item in any given group, instead of being used merely to indicate the attainment of a certain level of excellence. Raphael's masterpiece was the *Sistine Madonna*; the architectural masterpiece of Rome was St. Peter's. The next phase in the evolution of the word consisted in changes in the comprehensiveness of the groups to which it was applied, or in the principle by which they were selected; we encounter lists of the masterpieces of painting, from Cimabue to the present day; of the masterpieces of genre, in painting, sculpture, etching, and other arts; or of the masterpieces of art, from the Parthenon and the Iliad to Hamlet and Beethoven's *Fifth Symphony*. But it is noticeable that this change was accompanied by a tendency to use the word in the plural and to preface it with the adjective *great*; it was beyond human power to select a single unquestioned masterpiece from such vast fields—and for some obscure reason users of the word have tended to avoid applications of it that were sure to lead to controversy. *Great* involves innumerable problems in absolute aesthetic value and arouses endless arguments, but *masterpiece* indicates only relative values, and limited comparisons, and it is employed chiefly to record widely accepted judgments. For still more obscure reasons the word is applied much oftener to the various arts of space than to either music or poetry or the arts of the theater; it occurs most often, of course, in arts such as painting and sculpture in which there are no bars except lack of talent to the attainment of the highest possible level of artistic achievement. It must be recognized, however, that in all these fields the word has been losing caste in recent years. It is perhaps because its meaning has grown too flexible—we can say, for example, without arousing much argument, either that Vermeer left us no masterpiece or that he left few works that are not masterpieces—but it is more probably because our interest has turned from the superficial and rather fantastic problem of determining the precise rank of any given work within its group to the profounder and more realistic problem of analyzing its internal structure and realizing its individual potentialities, and because we are less intrigued by the notion of "permanent" values. We seldom find *masterpiece* in the index of any modern work on art and its appearances in the text are growing less frequent. When it does occur it is a little more likely to be used as a simple indication of value, or as a device for imparting color and rhetorical force to a sentence, than as a carefully considered superlative. It is still a permissible word, and even a respectable one, but under the pressure of the exacting modern standards for the study of art it is losing a little of its former glamour.

—C.T.

**master plan.** See CIVIC PLANNING.

**mastic.** As a varnish-making resin, this is probably the most commonly used of all such materials at the present time. Mastic varnish is ordinarily prepared from the pure resin by selection and solution with a solvent like turpentine, with the addition of a small amount of drying oil or other plasticizer. The resin is derived from the tree, *Pistacia Lentiscus,* native of the Greek Archipelago but found, also, in other regions of the Mediterranean. The best known commercial source is the island of Chios. See RESTORATION OF PAINTINGS.

—G.L.S.

**metabami** (Pers.). Celadon (q.v.).

**matelasse fabrics** (Fr. *matelasser,* to cushion, to cover). An interesting modern fabric used for ladies' high priced dress materials. These are compound fabrics and have two distinct series of warp and filling threads. The face shows a modeled surface or pat-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

tern in quite high relief. The back shows the complicated nature of the weaving.
—G.W.R.

**materialism.** Materialism in art must be understood as the representation of that which is taken exclusively from external nature, as it is perceived by our senses. The only focal point of this art is material nature, which has for its main characteristic, the accidental. This type of materialism began in the early 15th cent. with the brothers Van Eyck, Konrad Witz, and Hans Multscher. In this art it is important that the world which is perceived by our five senses is understood as of the last and highest value, and from which there is no appeal. The last theoretical conclusions were drawn by the French Encyclopedists of the 18th cent. (see Diderot's works, esp. *La Système de la Nature*). Since for them nature has no purpose, no order, no value dependent upon purposes or order lying outside natural objects and nature is the only thing existing, no beauty of art is possible. For beauty is a value arising in the human mind and fixed by it. Furthermore, materialistic art can have no ideals and cannot consider the ideal as the goal for which it strives. Upon the basis of this materialism the only purpose of art can be the representation of nature in its entire and accidental appearance. An art thus unmistakably achieved must consequently be entirely indifferent to the human soul. The more it succeeds in eliminating all human value, the more precious it becomes.

A complete achievement of this materialistic program in art is not possible, because the main requirement of art is unity; and unity is achieved by ordering all single parts into a system of balance. The characteristics of unity and balance are qualities not lying within the material itself but arising from the activity of the human soul.

The more materialistic art grew away from the principles of the Middle Ages, the more all spiritual aims tending beyond the represented object vanished. Approaching nearest to the materialistic program were the so-called Naturalists of the 19th cent., such as Courbet and Leibl, the Impressionists such as Manet, Renoir, etc., and the Pointillists such as Signac. Only these artists seriously tried to put upon the canvas exclusively sensual perceptions and to indicate them as of the highest values in themselves. In connection with these works it is interesting to notice how the artist tried to evade the problem of "form", and to conceal unity and balance in order to give the appearance of accident and self-sufficiency. —A.J.S.

**mathematical aesthetics.** See AESTHETICS, recent trends in (1).

**maxima.** See NOTATION.

**Maxwell discs, triangle.** See COLOR.

**Maya art.** The Maya were the greatest of ancient American peoples and their art was the finest of pre-Columbus American art. In fact, the three profound achievements of the Maya were art, architecture, and astronomy.

Although the astronomical data upon which is based the ultimate Maya calendar may have begun to be collected as early as the 7th cent. B.C., the Maya as an integrated, identifiable culture did not come into being until less than a hundred years before the birth of Christ. Suddenly, in the densely rain-forested plains of north-central Guatemala and neighboring British Honduras, the Maya were building splendid stone cities whose lofty truncated pyramids even today lift their ruined temple crowns as high as 280 feet in the air. Maya architecture was marked by the use of the corbelled arch. From their complex calendar the Maya carved dated inscriptions upon their towering monolithic stone monuments. Their writing-system was original, complete. Maya culture had flowered almost overnight. And with it, Maya art.

During the past hundred years Maya archeology has tended to emphasize the importance of the Petén area as the home of the so-called "Old Empire" of the Maya during the first five or six cents. A.D., and to bespeak the succeeding value of northern Yucatán as the site of the "New Empire", particularly between the 10th and 15th cents. A.D. The potential archeological value of the highland region of southern Guatemala has been neglected. Historically, this region

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

promises to yield much; artistically, the prospect is more problematical. Unquestionably, Maya art reached its apex in the "Old Empire" cities, particularly in Quirigua, Piedras Negras, Palenque, and Copán. It had a strong resurgence some centuries later in Chichén Itzá, in Uxmal, and in several lesser cities of the Yucatecan area.

Like Maya architecture, the Maya calendar, and the Maya system of writing, Maya art was intensively religious. This was logical in a hemisphere where all cultures based most of their personal and national conduct upon religion: that is, upon the propitiation of the strenuous forces of nature surrounding them.

Maya art was mature from its identifiable beginnings. It simply grew more complex as the Maya culture grew older. But in the process it lost its earlier freshness and realism. Increasing emphasis was placed upon geometric design. There was a steady formalization of the nature-motifs, resulting finally in the most stylized ornamentation of stone, wood, and clay achieved by any people.

Living in an area of luxuriant tropical growth, the Maya in their art reflected their surroundings. They included profuse quantities of decorative detail. Like nature itself, the Maya abhorred a vacuum, and usually endeavored to fill all blank spaces with design. In the world about them there was no lack of motifs, either in foliage, animal life, or astronomical phenomena. Despite the urgency of pleasing the gods of fertility, however, there was in the art of this agricultural people a marked lack of phallic symbolism.

High among examples of Maya art are the stone sculptures in the round and semi-round at their great eastern city of Copán, in present-day Honduras (particularly a maize-goddess whose original is in the British Museum); the huge monolithic sandstone monuments at Quirigua, in Guatemala, with their complicated carved designs and hieroglyphic inscriptions; the carved and painted walls at Chichén Itzá, in Yucatán, México; a magnificent bas-relief on three walls of a nobleman's tomb at Comalcalco, in the Mexican state of Tabasco; jadeite figurines and plaques of exquisite workmanship, dredged from the great Sacred Cenote at Chichén Itzá; and painted ceramics from the Usumacíntla valley between Guatemala and Mexico.

These, like all Maya art, were produced not by professional artists but by superb craftsmen. None of the ancient American nations supported an artist class. Their art was produced not as tours de force, not as the personalized expression of the artist, not on commission from some wealthy patron, but essentially as the conscious effort of the skilled artisan class to produce essentially utilitarian objects pleasing to the deities. In this, no people has been more successful. See ABORIGINAL AMERICAN ART.

—M.R.

**mazurka.** A national Polish couple dance usually performed by four or eight couples, in 3/4 or 3/8 time, the tempo being slower than the usual waltz. The basic step consists, in general, of leaping, sliding, and hopping combinations, with the greatest accent placed upon the second beat of the measure. When the dance was most popular, great freedom of invention was allowed, with the result that many mazurkas had a fresh, improvisational quality. —J.G.

**meander motif.** The meander (or fret) ornament, a simple, interlocking geometric pattern, was used in early Chinese art as a symbol of thunder and lightning; it is frequently found on Shang and Han bronzes. Among the Greeks it was employed to enliven architectural surfaces, especially on ceiling cornices and on the bases and capitals of columns, and as a border on vases. Several variations of the meander were devised, and sometimes a fret border was broken with insertions of squares or stars. —W.R.A.

**meaning.** As used in literary criticism, this term usually indicates the reference of the work of art beyond itself. The distinction involved here is that between the work of art as a formal and material structure, and what is conveyed by this structure. The concept of *meaning* thus depends upon the concept of *content* or *subject-matter*: the art work is regarded as referring to this content, and the meaning of the work is what it says about the content.

The term is also used, less often, to refer to the total effect produced by the work, without regard to the formal, material, or contextual elements of this effect. —I.J.

**mean-tone temperament.** See interval.

**measure.** *Mus.* A metrical unit of fixed length and accentuation, forming the smallest metrical subdivision of a period; presented

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

by a group of notes or rests contained between two bars; sometimes called a **bar.**

**measured music.** See MEDIEVAL MUSIC.

**measured painting.** In Chinese painting, architectural in landscape. Kuo Chung-hsi (ca. 985) was an expert in this form of painting.

**measuring point.** See PERSPECTIVE.

**mechanical arts.** Productive activities of man which require mechanical labor and consequently cannot be listed among the liberal arts (q.v.). This division which was universally accepted during the Middle Ages and very largely even during the Renaissance and baroque periods, has its origin in social conditions of classical antiquity. For according to ancient Roman thought, while it was desirable that a citizen and free man give his attention to the philosophical and political interests embodied in the liberal arts, the pursuit of activities requiring physical labour (i.e., of the mechanical arts) was proper only for slaves. So great was the conservatism of medieval Europe that in spite of fundamentally altered social conditions this obsolete classification was retained. Medieval man was compelled consequently to list all that we now call the fine arts (q.v.) among the mechanical, since they require physical exertion; he could exempt them from this classification only in so far as they presupposed the liberal art of geometry. Therefore, architecture, e.g., was a liberal art as long as in the stage of geometrical planning, but a mechanical art when in the stage of actual construction. To raise the standing of the artistic profession to the level of liberal pursuits was an important purpose of Renaissance theory. See paragone. —R.B.

**mechanical drawing.** A mechanically controlled process of drawing which intends to import specific information to the reader. The same term applies to the terms, drafting, engineering drawing and precision drawing. See drawing. —R.L.W.

**mechanical instruments** (musical). In a sense all instruments which produce sound are machines. They differ, however, in the amount of mechanism intervening between the operator and the sound produced. Thus the vocal mechanism is part of the human body, responding in an intimate fashion to the mood of the singer. The keyboard instruments are much more remote, since a very complex machine intervenes between the will of the operator and the sound produced. We must distinguish the extent to which various musical instruments are mechanized. In the first or simplest stage a musical instrument produces sounds when manipulated by a performer. (For a discussion of this subject see the article entitled MUSICAL INSTRUMENTS.)

A second stage is reached when part of the operation, usually accomplished by the performer, is mechanically realized. Thus the **English guitar,** a stringed instrument which was played by a plectrum held in the fingers of the right hand, was in certain examples of late date automatically plucked. All the player did in such instances was to depress a key (like a small piano key) above the proper string to set the plucking mechanism into operation. In a sense the **harpsichord** and **piano** must be included here, since the ancestors of these instruments were sounded by plucking the strings with a plectrum or by striking them with small hammers. In another group of instruments the pitch of the sounds produced is controlled by operating a button or lever. A familiar though musically unimportant example of this group is the **auto-harp** where accompanying chords are automatically stopped by depressing a button.

Finally we reach a group of instruments which are completely or almost completely automatic, human intervention being essentially limited to setting the mechanism in operation and stopping it. Here we must include self-playing keyboard instruments, music boxes, and the like. This is the group which is usually designated by the term "mechanical instrument", and it is to this group that this article is chiefly devoted. The phonograph and radio (q.q.v.) are separately dealt with under the appropriate headings.

The tale of the *Golden Cockerel* of Pushkin with its magic bird which could forewarn of invasion, the mechanical nightingale of Andersen's fairy stories like many early tales of wonder reflect a deep desire to impose man's will on the most impalpable element as well as a naïve wonder which assumes that mechanisms which sing must be magic. Historical automatic instruments evolved at an early period and continued to follow a relatively uniform pattern through the period of Beethoven and (with diminshed importance) to the present. The **automatic harpsichord** of the 16th cent. and the modern Swiss music box are closely related as far as the essentials of the action are concerned.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

A series of pipes with their appropriate valves or a harpsichord mechanism were actuated by projecting studs on a revolving barrel. Père Engramelle in his very curious volume, *La Tonotechnie*, Paris, 1775, describes the manner of pricking the studs on the barrel with clarity. "Notation as I shall teach it, is nothing else than an easy system of calculating music, of measuring notes by figures, and of dividing the circumference of the cylinders in as many equal parts as may be necessary, in order to apply nails to them at precise and regular intervals, and to arrange them in such a fashion as to execute with taste and precision the pieces of music which one wishes to have played by these machines."

The invention of this mechanism dates back to the 16th cent. at least. Athanasius Kircher (*Musurgia*, 1650) describes a glockenspiel with a self-playing mechanism. Mersenne (*Harmonie universelle*, 1638) who was familiar with the device seems to consider it a German invention and refers to it as "of our time". Earlier than these descriptions, however, is an actual automatic instrument of the 16th cent. constructed by the Augsburg organ builder, Samuel Biderman. This, like the hurdy-gurdy, was operated by a crank, and the cylinder was pricked, producing six pieces of music. The wonder with which a modern listener might hear this echo of the music of so remote a period had already been felt by Père Engramelle who wrote a prophetic paragraph concerning the possibility of preserving the sound and the style of music by earlier composers, a possibility which we still have only partially realized with the phonograph, a much more perfect instrument at our disposal.

"We would still enjoy at present the execution of Lulli, of Marchand and of all the great men who have filled their contemporaries with astonishment if they had understood the system of pricking their best pieces, which transmitted by themselves to posterity on unalterable cylinders, would have preserved this form of expression of which we can only form an idea through history."

This wish to preserve the performances of famous performers was no doubt the force which inspired the unknown inventor who described "a Machine that shall write Extempore Voluntarys or other Musick as fast as any Master of Musick shall be able to play them upon an Organ Harpsichord &c." in an anonymous manuscript of the 18th cent. Each key was to have a stylus on its lower surface which would trace straight lines on a roll of paper revolving under them. The length of each traced line would indicate the duration of a note, and its position from left to right the pitch. The resulting record would resemble a player-piano roll, and, indeed, this unknown inventor would seem to have anticipated certain basic elements of the later player-piano.

The famous engineer Samuel de Caus in a book at once naïve and ingenious (English translation entitled *New and Rare Inventions of Water Works*, 1701) proposed various musical devices operated by water power. Thus, for example, a bird whistle might be operated by the air pressure produced by admitting water from an upper reservoir into a lower air-filled reservoir. He also describes **water-organs** in which both the barrel mechanism and the bellows are actuated by a water-wheel, the latter by a crank action so that one bellows is deflated while the other is inflated. Such toys, no doubt, were intended to add to the pleasure of formal gardens of the period.

One must note that the best of these early devices were by no means inflexible and terrifying mechanisms like the early player-piano, but were gentle in tone; and one must further note that the controlling cylinders were not laid out in a mechanical fashion, but were so calculated as to produce effects of rhythmic nuance. That great composers did not despise such machines is shown by Haydn's music for the tiny flute-like pipes of a mechanical clock, by Mozart's *Fantasia*, better known in the version for organ but originally for a mechanical instrument, and Beethoven's *Battle Symphony*, originally composed by Maëlzel's Panharmonicon.

This early art survived in such pretty toys as the **Swiss music box** in which the actuating pins plucked slender vibrating metal tongues of various lengths. The motive power was supplied by a clockwork motor. The principle also survived in the **hurdy-gurdy** which was operated by a crank and which contributed to the spice and variety of street noises. The **barrel organ** invaded even the parish churches of England as readers of Thomas Hardy's charming tale *Absentmindedness in a Parish Choir* will recall. We find as distinguished a figure as Edward F. Rimbault recommending a variant of this mechanism, concluding "we need scarcely point out the superiority of an accurate mechanism over the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

imperfect manipulation of an inferior performer".

The 19th and early 20th cents. marked the full development of new types of player mechanisms adapted to the piano. Earlier types were operated by two treadles which were alternately depressed. The barrel of earlier examples was replaced by a roll of paper perforated by dots and slots of various lengths. These openings permitted a pneumatic apparatus to actuate the appropriate key for a duration corresponding to the length of the slot in the roll.

Early examples were formidable indeed, and capable of boundless technique. In spite of an almost complete lack of nuance (the levers or other controls which supposedly provided expression were unable to alter the fundamental rigidity of the instrument) these instruments proved attractive not only to the general public but to certain composers such as Hindemith and Casella who wrote music for the instrument. A newspaper clipping of the early years of the 20th cent. pictures the vogue for these machines in an amusing fashion and at the same time points shrewdly to a real function of reproducing instruments. "A music festival is really hardly needed this year, with so many free concerts given to the public by the agents of automatic piano players. . . . Almost every week it is announced that some piano-making firm is to put a new kind of self-player on the market, and the purchaser, who finds it hard enough already to choose a piano, will be more and more embarrassed in selecting among the many playing attachments, of which the pianola was the pioneer. . . . It is precisely in supplying this general lack of opportunity for the frequent hearing of good music that the self player finds its field of utility."

Later developments resulted in such instruments as the Duo Art and the Ampico in which the rolls were the reproduction of a performance by a performing artist. The mechanism was actuated by an electric motor and a greater range of expression was striven for. Partly due to inherent defects but chiefly to the phenomenal development of radio and the electric phonograph these instruments have ceased to play an important role. The **juke box**, an electric phonograph with a record selector and a nickel-in-the-slot attachment, furnishes a loud and strident musical background in saloons, road houses, and other places of entertainments where the player-piano used to flourish. In another musical sphere the radio offers a far wider variety of musical fare than was possible on the earlier instrument. The mechanical age in music has been succeeded by an electrical age which is still revealing its possibilities.

**medallion carpets.** See ISLAMIC ART.

**mediant.** *Mus.* The third note of any major or minor scale, the "middle" note between tonic and dominant. See idiom B(1).

MEDIEVAL MUSIC: *The Monodic Ecclesiastical Phase.* The initial stages in the development of ecclesiastical music, more specifically the **plainsong**, or sung prayer of the Church, are intimately connected with the beginnings of Christianity. The term plainsong (L. *cantus planus*; Fr. ***plainchant.***) meaning unaccompanied, unisonous, monodic, unmeasured melody, is a generic one, and includes the chants of the East (Armenian, Byzantine, Coptic, Ethiopian, Russian and Syrian) as well as those of the West (Ambrosian, Gallican, Gregorian, and Mozarabic). Since Christianity originated in the East, it follows that the sources of early Christian music are connected with those localities of the new religion in its inception—Jerusalem, Antioch, and Alexandria (see eastern chants).

The adoption of Hebraic forms of worship, e.g., the Alleluia, a direct outgrowth from the Hallel-psalms, and the Trisagion or Thrice Holy (the *Kedushah*), is an indication that Hebraic melodies were utilized by early Christians.

The spread of Christianity in the East brought the chant in contact with Greek musical theory and the Greek language, the liturgical language of the Church in both East and West up to the end of the 3rd century. The inclusion of the Kyrie into the Mass, the celebrated **Oxyrhynchus hymn** (q.v.) dating from the close of the 3rd cent. A.D., and the astounding similarity between the Greek hymn, Epitaph of Seikolos (variously dated from 2nd cent. B.C. to 1st cent. A.D.) and the Gregorian antiphon, Hosanna filio David —all of these constitute concrete evidence of the Greek influence.

The diverse Hellenic and Oriental elements were fused and crystallized by the Byzantine Church whose tendencies in the intellectual and religious spheres strongly affected the Roman Church of the West. Although the East continued to exert its influence with varying force on the West up to

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

the middle of the 8th cent., it is at present impossible to determine the extent and the precise nature of that relationship. The first complete development of liturgical chant is to be found in the East, but it is the Western Chant which represents the earliest efflorescence of music known to us.

To the Hebraic, Greek, and Byzantine factors in the development of the Western Chant must be added another—the Latin language which dominates the rhythmic flow of the melodies. That Roman secular melodies found their way into the chants when Christianity was Latinized in the West, is probably, though not demonstrable.

Before giving an account of the Western Plainsong, it is well to consider the attitude of the Church toward music. The master-motive of the Christian Church was salvation. To this end the arts were pressed into service. As has been already intimated, the development of the liturgy is identified with the rise of the Chant. The function of melody, then, was to enhance and make more potent the meanings of the liturgical text. The notion of music as an end in itself was associated with evil and therefore, vehemently rejected. The memorable words of St. Augustine at the time of his conversion sum up the outlook of the middle ages thus: "Yet again, when I remember the tears I shed at the Psalmody of Thy Church, in the beginning of my recovered faith; and how at this time, I am moved, not with the singing, but with the things sung, when they are sung with a clear voice and modulation most suitable, I acknowledge the great use of this institution. Thus I fluctuate between peril of pleasure, and approved wholesomeness; inclined the rather (though not as pronouncing an irrevocable opinion) to approve of the usage of singing in the church; that so by the delight of the ears, the weaker minds may rise to the feeling of devotion. Yet when it befalls me to be more moved with the voice than the words sung, I confess to have sinned penally, and then had rather not hear music." (*Confessions* xxxiii, 50).

It has been properly maintained that the four great chants of the West—the **Ambrosian, Gallican, Gregorian** and **Mozarabic** represent four dialects of a common language. Tremendous interest centers around the plainsong of the west not only because of its intrinsic value—one of the greatest artistic manifestations of the middle ages—but also because the Chant later constitutes the basis for the new polyphonic art which emerges about the 9th cent. and reaches its climax with the great 16th cent. polyphonic schools. The Gallican chant was superseded by the Gregorian when Charlemagne imposed the substitution of the Roman rite in 803 at the Council of Aachen. In Spain the Mozarabic Chant persisted for a time even after Alphonso VI (1085) against much opposition ordered the adoption of the Roman. There are little or no remains of the Gallican chant except for what was absorbed in the Gregorian. These include the *Improperia,* the *Crux fidelis,* and the hymn *Pange linga . . . certaminis,* all of which are part of the Good Friday service. Similarly, the Mozarabic chant did not survive except for 21 melodies, mostly from the Office of the Dead.

Named after St. Ambrose, Bishop of Milan (c. 340-97), the **Ambrosian chant** embraces all the music of the Milanese liturgy, a considerable amount of which was composed after the death of the saint. Although the Ambrosian Chant has survived, it has never been widely diffused, confining itself for the most part to Northern Italy. It was also used in the monastery of Monte Cassino up to the middle of the 11th cent. when it was replaced by the Gregorian chant. In spite of its antiquity, the earliest MS containing Ambrosian chant dates from the 12th cent.

Many Ambrosian melodies have found their way into the Gregorian collection. Indeed, the relationship of the Ambrosian to the Gregorian is reciprocal rather than one-sided. Comparative study of similar ornate chants reveals that the Ambrosian version tends to be more ornate than the Gregorian. On the other hand, the simple chants of the former are even simpler than those of the latter.

By far the largest and most important collection of ancient ecclesiastical music is that of the service of the Roman Church, or the **Gregorian Chant** (after Pope Gregory). This vast collection falls into two divisions, the music of the Mass (q.v.), contained in the Gradual, and the music of the Daily Hours of Divine Service in the **Antiphonary.** The texts for the first are available in the modern **Missal,** those for the second in the modern **Breviary.** The bulk of the music of the Proper of the Mass dates from the turn of the 7th cent. or earlier. The remainder was composed in the following centuries, some as recent as the 15th cent.

Of the role played in the development of the chant by Gregory's predecessors little is known. It appears that a papal school for singers existed in Rome at the time of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Pope Sylvester (314-36). Celestine I (422-32), Sixtus (432-40), Leo the Great (440-61), Gelasius (492-96), Symmachus (498-514), Hormisdas (514-23), John (523-26), and Boniface (530-32) are all said to have contributed to the liturgy and chant in some form or other. It is certain that the papacy at Rome furnished the impetus toward unity in the liturgy and chant. The climax in this direction came with the so-called Gregorian reform. According to a tradition based on the writing of John the Deacon (c. 872), Egbert, Bishop of York (732-66), and others, Gregory "arranged for the singers a most useful collection, the *Antiphonarius Cento*", made the liturgical chant equal to the liturgy itself as law of the Church, and imposed a uniform ritual and chant on all western congregations. The nature of Gregory's reform is disclosed in the meaning of the word *cento*, patch-work, hence compilation. With some additions made in the following centuries, this codification still constitutes the great body of Gregorian chant in use today.

The mission of St. Augustine in 596 to England at the behest of Gregory was but one important step in the propagation of the Romon chant in that country. In general, with the spread of the Church over Europe, the diffusion of the chant followed. On the continent the famous monasteries of Metz and St. Gall founded *Scholae Cantorum* based on the Roman model. By the 9th cent. the Roman chant was firmly established in Gaul through the medium of monasteries, cathedral and parochial schools. To be mentioned also are the monasteries of Reichenau, Fulda, and Cologne and Worms. In France the Abbey Würzburg and the schools in Mainz, Aachen, St. Martial in Limoges took a leading role in the dissemination of the chant. By the end of the 11th cent., Gregorian chant had established itself in Spain.

The concordance of the numerous MSS. preserved in these monasteries and schools from the 9th cent. on, demonstrates first the extraordinary zeal for unity in the chant and liturgy on the part of the Church, and 2nd that they must have been copies of an original collection stemming from the lost *Antiphonarius Cento* of Gregory I.

During the early centuries, the Chant was transmitted by oral tradition. *Neums* (q.v.) based on the grave, acute and circumflex accents (of probable Byzantine origin) indicating the rise and fall of a melodic line were used to recall known melodies. The shortcomings of such a method of notation were manifest to many medieval musicians. Numerous efforts were made to establish a system of precise notation. Among the systems of notation in vogue was the *daseian* notation (9th cent.) in which letters in various positions represented different pitches. That of Hermannus Contractus (1013-54) in which letters were used to indicate melodic intervals was somewhat similar in principle. The staff notation favored and perfected by Guido D'Arezzo (c. 995-1050), was really one among many in use at the time. Guido's interests were those of the practical teacher and musician. His method of **solmization** (q.v.) and adoption of the syllables ut, re, mi, fa, sol, la for the notes of the hexachord are unique achievements of far-reaching consequences.

Medieval music is based on a system of eight modes—4 authentic modes, and 4 derivative plagal modes. (See modes, ecclesiastical.) In modern chant books the mode is indicated by its appropriate number at the beginning of each composition. There is substantial evidence that the medieval modal system was in reality super-imposed on the Church melodies the basis of which is pentatonic. (See pentatonic scale.) The presence of the ***quilisma*** (a jagged note to be sung softly) occurring within the minor third adds weight to this view. The quilisma acts as a filling-in-tone, or non-essential tone which gives diatonic character to the fundamentally pentatonic structure of the ancient melodies. That numerous chants were revised in order to make them conform to the modal system is certain. Although theory and practice are sometimes at variance, for practical purposes it is best to treat the chants according to the modal system.

From the viewpoint of melodic structure plainsong falls into two styles: 1st the syllabic style in which for the most part each syllable of the text is set to one note, with an occasional syllable set to 2 or 3 notes, and 2nd the melismatic in which the syllables are set to 2 or more notes, and groups of notes. In general the capacity of the singers and the significance of the occasion determine the style.

The greater portion of Gregorian chant is either *responsorial* or *antiphonal*. (See psalmody.) The responses of a group to a soloist characterize responsorial chant. Representative of this category in the Mass are the **Gradual** (*Gradualresponsorium*) and **Alleluia**, in the **Office**, the **Respond**, (*Responsorium*). The alternate singing of two groups is the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

essential feature of antiphonal chant. This type is found in the Introit, Communion and in a certain sense the Offertory. More elaborate than the antiphonal chants of the Office, those of the Mass were performed by trained singers. Belonging to neither the responsorial nor the antiphonal is the **Tract** (*tractus*—straightway) in which the text is sung directly from one end to the other without alternation.

To the 9th cent. must be credited two of the most outstanding developments of medieval music, the *sequence* and the *trope* (q.q.v.). In the Alleluia it was customary since pre-Gregorian times to sing a long melismatic passage on the final syllable "a". This wordless melody was known as a ***jubilus*** or jubilation. Historians have attributed to Notker Balbulus (the stammerer), monk of St. Gall (d. 912) the mnemonic device of supplying these *longissimae melodiae* with words. The adaptation of words to a jubilus was called *sequentia cum prose.* (By the 12th cent. the terms prose and sequentia appear to have been used interchangeably.) In his *Liber hymnorium,* Notker states that he followed the example of the monks of Jumièges, who in turn probably obtained the idea from Byzantine sources. It appears therefore, that the sequence originated in northern France. Notker apparently was a writer of words to pre-existing melodies rather than a composer.

The trope which legend associates with Tuotilo, monk of St. Gall (d. 915) was an interpolation or addition in the chant. Of Byzantine origin this practice gradually penetrated the Ordinary of the Mass, and the Hour services. The interpolated melismatic melodies were later set to a text usually appropriate to the character of the feast according to the principle—one note, one syllable. Thus the sequence can be regarded as a trope appended to the Alleluia. Both tropes and sequences continued in vogue for several centuries. The former, never attained a place in the liturgy, while the latter after achieving a popularity which menaced the integrity of the liturgy were banned by the Church with the exception of 5.

There was little difference in musical style between the chants of the 9th cent. when new feasts were added and those of Gregorian times. As the need for new texts arose, the older melodies, or segments of them were utilized. The compositions of the 11th and 12th cents., on the other hand, no longer attained the simplicity, depth, and robustness of the primitive melodies. Affectation and histrionics replaced sincerity and sobriety. The seeds of decadence were already in evidence during the 9th cent. when the new art of polyphony was first practiced in the Church. With the emergence of measured music during the 12th cent. came a misunderstanding of the Gregorian melismata. The rapid diffusion of the chant during the 9th, 10th, and 11th cents. is another cause which contributed to its decline. No sooner was the supervision of Rome relaxed in distant parts of Europe than the execution of the chant suffered. As the impetus in the cultivation of polyphony gained momentum, the interpretation of the chant became more and more uncertain.

After some centuries an abortive attempt to "reform" the chant resulted in the Medicean Gradual of 1614-15 in which the primitive melodies were abbreviated and shorn of their rich melismas beyond recognition, and interpreted according to the rules of measured music. Knowledge and interest in the Gregorian chant was so meagre in the years that followed, that no reaction against the crudities of the Medicean editions occurred until the 19th cent. The credit for the revival of Gregorian chant goes to the Benedictines (Solesmes) of the Congregation of France, especially Guéranger (1805-75) Pothier (1835-1923) and Mocquereau (1849-1930). "Where the MSS of different periods and different countries agree in their version of a melody, it may be affirmed that the true Gregorian text has been discovered." With this rule as guiding principle, an intense comparative study of hundreds of MSS from the 9th to the 14th cents. led to the restoration of the ancient Church melodies. In 1889 Mocquereau started the monumental *Paléographie Musicale* containing facsimiles of Ambrosian, Gallican, Gregorian and Mozarabic MSS., as well as studies on the history of the chant and its interpretation. The researches of the Benedictines received ecclesiastical sanction in the *Motu proprio* (Nov. 22, 1903) of Pius X, which provided for an *Editio Vaticana* (1905) containing the authoritative version of the Gregorian chant.

A theory of rhythmic interpretation has been developed by Mocquereau based on the equal duration of the square punctum and the virga. According to this theory note-groups of 2's and 3's freely mixed make up the rhythmic flow. The 1st note of each group bears an ***ictus*** which is sometimes indicated by a vertical line (|) or implied by the con-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

text according to well-defined rules. The ictus however, does not express any material emphasis being independent of the Latin tonic accent. "The ictus is more in the mind than in the voice" is a Solesmes slogan.

The vast labors of the Solesmes school have brought to light once more the ancient melodies, but while conceding the beauty of the Solesmes interpretations many scholars do not agree with their rhythmic principles. The so-called **Accentualists** (Pothier) who maintain that verbal accents should be stressed in rendering the chant, and the **Mensuralists** (Dechevrens, Jeannin) who insist that the note values of the medieval MSS. indicate longs and shorts (long twice duration of short) both find support for their contentions in medieval theory. Because the plainsong passed through various stages during its long course, it is doubtful if a general agreement on rhythmic interpretation will ever be reached. In any event, there is still much important work to be accomplished in this direction. The "Old Vatican Music" MSS. allegedly containing late copies of pre-Gregorian chant remain for the greater part a field for investigation.

*The Monodic Secular Phase.* That secular music has existed at all times requires no proof. In contrast to the survival of sacred music, no secular music of the early Middle Ages is now extant. There was no necessity for an oral tradition resembling that of the Church. MSS. of the 9th-11th cents. in staffless neume notation containing non-liturgical songs in Latin are undecipherable. Of the music of the **goliards**, wandering students and minor clerics—drinking songs, satirical songs, etc.,—nothing is known. With the exception of one melody, if it can be called such (*Audigier*, incorporated in the pastoral play by Adam de la Hale), nothing of the music of the ***chansons de geste***, epic narratives on the exploits of Charlemagne, Roland, etc., remains.

It is quite different with the songs of the **troubadours** and **trouvères** whose sophisticated art coincided with the Age of Chivalry from the end of the 11th cent. to the end of the 13th. Over 250 melodies and 2600 poems by the troubadours are preserved in various MSS. The trouvères were more fortunate in the survival of their works—some 1200 melodies and about 4000 poems, in many cases more than one melody to the same poem. This outburst of monodic song must be considered in the light of the crusades, the stimulating contact with the east, and the use of the vernacular languages. The new art brought with it a new theme—chivalric love, fealty, and service.

*"A Dieu mon âme,*
*Mon coeur aux dames,*
*Ma vie a roi,*
*L'honneur pour moi."*

In reflecting the varied thoughts and feelings pertaining to the mundane aspect of medieval life, troubadour and trouvère art for the first time in history emphasized the role of music as an end in itself.

The troubadours, amateur musician-poets of noble birth first practiced their art in the ancient province of Limousin, south of the Loire (Provence). Their language was the *langue d'oc*. The trouvères who imitated them came from the north of the Loire. Except for the use of the *langue d'oïl* there is no essential difference between the music of the trouvères and that of the troubadours. The cultural contact which paved the way for the art and ideas of the Provençal poets in northern France was effected during the second Crusade of 1147 when the nobility of the north and south was brought together. Practiced originally in the courts of Provence and the French court at the time of Louis VII, secular monodic art soon found its way into the feudal court of Burgundy, the Spanish courts of Aragon and Castile, as well as those of England and Italy.

According to all accounts, Guilhem IX, Duke of Aquitaine (1071-1127) was the first troubadour. Among the more famous were Marcabrun (c. 1120-95), one of the first to cultivate that obscure genre called ***trobar clus*** (closed poetry i.e. obscure) containing secret forms of verse accessible only to the initiated, Bertran de Born (d. 1215) who took part in the struggle between Henry II of England and his rebel sons, Peire Vidal (d. c. 1215) a rash scatterbrained individual known as "terror of husbands", Guiraut de Bornelh (d. c. 1220), *lo maestre dels trobadors*, and Folquet de Marseilles (d. 1231) who from being a troubadour ended his career as bishop of Toulouse. Also to be mentioned are Jauffre Rudel (1st half of 12th cent.), Raimon de Mirval (d. c. 1220) and Raimbaut de Vagueiras (d. 1207). Greatest of all troubadours was Bernard de Ventadour (d. 1195) who rose into prominence at the court of Eleanor of Aquitaine, grand-daughter of the first troubadour, and whose perfect specimens of love poetry are wedded to veritable melodic gems.

Included among the trouvères were Chré

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

tien de Troyes (12th cent.), Châtelaine de Coucy (fl. c. 1186-1203), Gace Brulé (d. c. 1220), Quesnes Béthune (1150-1224), and Blondel de Nesle (12th cent.) associated with Richard-Coeur de Lion (1157-99), himself a trouvère. Actual performance of the songs was in the hands of the wandering ***jongleur,*** a peculiar combination of executant musician and mountebank, who in return for wages placed his talents at the disposal of the troubadour (or trouvère). To the accompaniment (probably consisting of a simple prelude and postlude), of the harp, veille, guitar, lute or even a small portative organ, the jongleur performed his master's songs from castle to castle.

The relation between troubadour and jongleur was much like that of knight and squire. Occasionally the lowly jongleur wrote and composed, and thus raised his status as in the case of the troubadours Bernard de Ventadour and Gaucelm Faidit (d. c. 1216), and the trouvère, Colin Muset (c. 13th cent.). By the 13th cent., however, the distinction in social status between jongleur and trouvère appears to have no longer existed. During the 13th cent. supremacy in the art of song shifted to the *bourgeois* school of Arras, the most outstanding being the trouvère, Adam de la Hale (c. 1238-88), author of *Jeu de Robin et Marion,* the earliest French play with music.

The theory that the songs of the troubadours were originally imitations of Spanish models which in turn were based on Arabic forms must be dismissed. Despite its plausibility in view of the fact that the lute, a favorite of the troubadours, is of Oriental origin, the complete lack of Arabic MSS. renders this theory untenable. One must turn to the forms practiced by the Church—the litany, the rondeau, the sequence and the hymn—as the derivative elements of troubadour-trouvère lyrical poetry. The popularity of the sequences, tropes, and hymns naturally led secular artists to similar forms of expression. The themes of love and service, on the other hand, had their antecedents in medieval Latin poetry. They had but to await the Crusades for the full flowering.

As the following listing of poetic types will show, the subject matter included themes other than love and service. The ***canso*** or ***chanson d'amour*** treated love according to the *"théorie de l'amour* courtois", the ***sirventes*** of moral and political topics, the ***pastourelle*** of the love adventures of a knight with a shepherdess. The ***alba*** or ***chanson d'aube*** was a song of warning in which the lovers were informed that the dawn was approaching. The ***chanson de danse*** (***estampie***) as the name suggests, combined song with dance. More complex were the ***partimen*** (***jeu parti***) and the ***tenson,*** debates between two interlocutors, sometimes on a moral or political subject, sometimes on a point of amorous casuistry. The ***chanson de toile*** supposedly sung by a woman at work treated of unhappy romance. To be mentioned also are the crusaders songs and the ***planh,*** a dirge on the death of a hero.

The most prevalent musical form may be described as A-A-B. This simple formula was capable of infinite variation. Indeed it was the rule that no two songs should be alike—the slightest dissimilarity satisfied this canon. The first strophe, A frequently ends with a half-close—*ouvert,* and the antistrophe A set to the same melody with a full-close —*clos.* The episode B set to a different melody may be short or long and is often subdivided.

Different from the above in form are the ***rondeau*** and the ***descort*** (***lai***). The former may be described by the following formula:

music: A-B-A-A-A-B-A-B
text: a-b-c-a-d-e-a-b

Lines a-c-d and lines b-e have the same meter and the same rhyme. In the *descort,* on the other hand, each verse possesses a different setting.

The ecclesiastical modal system is the basis of the melodies, but many of them border on those modes scrupulously avoided in church music—the major and the minor. In the various ***chansonniers*** of the 13th and 14th cents. which preserve the songs, the plainsong notation on staves is used. Since this type of notation indicates no time values, the interpretation of rhythm has caused considerable difficulty. The most widely accepted solution to this problem (formulated by Jean Beck and Pierre Aubry) is that the poetic meter of the text determines the rhythm of the melody. Through the application of the *rhythmic modes* (q.v.) the melodies acquire real meaning. Balanced phrases four measures in length (sometimes six), the prevalent feature of modern music are common.

The art of the troubadours was stifled by the Albigensian crusade (1209-29). This implacable war carried on by Innocent III against the Provençal nobility who constituted an anti-sacerdotal party in opposition to the Roman Church, resulted in the complete destruction of Provençal civilization

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

"Song should express joy, but sorrow oppresses me, and I have come into the world too late," mournfully wrote Guiraut Riquier (d. 1292) last of the troubadours. The decline of the trouvères was a gradual process, social changes and interest in the new art of polyphony both playing their inexorable roles.

With Guillaume de Machaut (c. 1300-77) monodic song experienced a momentary resurgence in France. But the great days of the Age of Chivalry were over, and Machaut's songs were really an emulation of the past and not a reflection of contemporary mood. Machaut's monodic *lais* consist of 12 pairs of stanzas, each having a different metrical form and melody with the exception of the last which is the same as the first in meter and is set to the same melody. His ***virelais*** (***chansons balladées***) are based on a form frequently found not only in troubadour and trouvere songs but also in the non-liturgical songs of the 13th and 14th cents. In its simplest form the *virelai* (also equivalent in form to the Italian ***ballata***) answers to the following formula: Music: A-B-B-A
Text: a-b-c-d.

The German counterpart of the troubadour and trouvère is the **Minnesinger** (Minnelove). Using the lyrical forms of the troubadours as their models and in some instances fitting German poems to Provençal melodies, the Minnesingers are by no means to be considered as slavish imitators. They are as thoroughly German in spirit as the courts of the Hohenstaufen, Thuringian, and Austrian nobility which they graced.

Outstanding among the Minnesingers, as a rule members of the lower nobility, were Friedrich von Hûsen (c. 1190), Walther von der Vogelweide (c. 1170-c. 1230), most famous of German medieval poets, his great contemporary, Wolfram von Eschenbach, Neidhart von Reuenthal (c. 1180-1250), and Ulrich von Lichtenstein (c. 1200-76). Of especial interest is Heinrich von Meissen (1250-1318), better known as Frauenlob (ladies' praiser), who is said to have established the first guild for singers at Mainz in 1311. The Minnesingers did not have jongleurs, they performed their own songs.

In their praise of love and gallantry, the Minnesingers assumed a chaster attitude than the troubadours and trouvères. Their poems were permeated with a feeling for nature and a religious mysticism totally foreign to the skeptical and volatile tone of their western confrères. The songs in honor of the Virgin Mary are typical of a religiosity peculiarly German.

Practically identical are the poetic types: the ***Lied*** corresponds to the *canso*, the ***Leich***, the *lai*, the ***Tagelied***, the *alba*, etc. The ***Spruch*** usually didactic in character, dealt with social and political matters. The most frequently used form consists of a couplet and a conclusion i.e. two ***Stollen*** and the ***Abgesang***. The two *Stollen* are metrically alike and set to the same melody. The *Abgesang* has its own melody, thus making an A-A-B. In some songs there is a repetition of the couplet melody following the *Abgesang*.

Based on the ecclesiastical modes, the melodies show the influence of Gregorian chant. Like the melodies of the troubadours and trouvères, those of the Minnesingers are interpreted rhythmically according to the meter of the verse. (See rhythmic modes.) In melodic invention and sheer beauty, the art of the Minnesinger as a whole compares less favorable with that of his western colleagues.

With the decline of feudalism and the extinction of the Hohenstaufen dynasty in the 14th cent. the art of the Minnesinger began to dwindle. Hugo von Monfort (1357-1423) whose texts were set to music by Burk Mangolt and Oswald von Wolkenstein (c. 1377-1445) represent the movement at its lowest ebb.

The rise of the middle class brought with it the ***Meistersinger***. Following the example of Frauenlob, the Meistersingers started schools and formed guilds for singers at Mainz, Strassburg, Frankfort, Nuremberg and other German cities. The Meistersingers professed to follow the ideals of the Minnesingers, but their songs are extremely stilted and pedantic, the result of a meticulous observance of complex rules. The most important Meistersinger was Hans Sachs (1494-1576), the cobbler of Nuremberg, immortalized by Wagner in his great music-drama.

*The Monodic Non-Liturgical Phase.* The line of demarcation between religious and secular song is often times difficult to draw. Many of the troubadour-trouvère songs are religious in subject matter. Ever since the earliest times the secular and the religious inter-penetrated. The meeting of the two is to be observed in non-liturgical song. In northern Italy about the middle of the 13th cent. monodic song took the form of the ***lauda spirituale***, a non-liturgical song of praise. Sung by the flagellant fraternities in the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

course of their pilgrimages, the *lauda* is folk-like in character and its rhythms show a remarkable kinship to those of Gregorian chant. The form of the *lauda* approaches that of the French *virelai*.

The flagellant fraternities gradually spread to the north extending as far as the Rhine provinces. During the period of the Black Death in 1349, the penitential mania reached its climax. In Germany flagellants included in their penitential rites the singing of ***Geisslerlieder*** (Geissler-flagellants), the verse forms of which were modelled on the Italian *lauda*.

Somewhat allied to the *lauda* is the ***cantiga*** some 400 of which were collected under the aegis of Alfonso X (*el Sabio*) of Castile and Leon (1252-84) famous patron to many Provençal troubadours. The *cantigas*, songs in praise of the Virgin Mary, are written in the Portuguese-Galician language and most frequently follow the melodic pattern of the French *virelai* or the *rondeau*. In the MS. containing the *cantigas* are several minatures showing various instruments, some of Arabic origin such as the lute, rebec, etc., thus implying a Moorish influence. It is fallacious, however, on this and other circumstantial evidence to jump to the conclusion that the Moorish element was the dominating influence not only in Spain but in Europe as well. Another miniature indicates that some of the *cantigas* were accompanied by dance—not an unusual fact considering the importance since the earliest times in Spain of the dance in popular religious worship.

Religious pilgrimages to famous shrines such as the monastery of Monsserrat claimed to be the legendary site of the Holy Grail account for some monodic pilgrim songs of popular origin (*Cants dels Romeus*) dating from the 14th cent. These songs dedicated to the Virgin and written partly in Latin and partly in Catalan also combine communal dancing with religious worship.

*The Polyphonic Phase.* The art of polyphony in its mature stages constitutes one of the great achievements of western civilization. For the first few centuries its development was mainly the work of monkish musicians, but its origin lay outside the Church. The writings of Bishop Aldhelm (c. 640-709) and Johannes Scotus Erigena (c. 815-c. 877), the Irish theologian-philosopher, indicate that part singing was practiced at least as far back as the 7th cent. in England and Ireland. In his discussion of Welsh music Giraldus Cambrensis (1147-1220) stated that the long-standing popular practice of part singing was transplanted from Denmark. Although it is possible that some form of primitive polyphony was known elsewhere in Europe the evidence points to a northern origin. The introduction of popular polyphony into the Church was no doubt a concession to a persistent practice.

The earliest form of polyphony practiced in the Church is known as ***organum*** (or diaphony as it was also called). It is described in a treatise entitled *Musica Enchiriadis* of unknown authorship, though attributed by some to Hucbald (c. 880), Benedictine monk of St. Amand. Organum consisted of a Gregorian melody accompanied by another which proceeded in parallel motion at the 4th or at the 5th above. This crude form of polyphony was undoubtedly improvised.

Later the term organum became a generic one applied to various forms of primitive polyphony. In all its forms the unison, the octave, the 5th and the 4th served as consonances. An immense step forward in the direction of genuine polyphony was taken when Johannes Cotto (c. 1100) strongly advocated the principle of contrary motion. Theory usually lags behind practice, for this procedure appears to have been used at least a century before in the Winchester Troper, an English MS. written in neumes in ***campo aperto***, i. e., without lines. Admitted by Johannes de Garlandia (early 13th cent.) and given complete sanction by Walter Odington in 1280 as imperfect consonances, major and minor 3rds were comparatively late comers into the family of consonances. In the final recognition of 3rds and 6ths as consonances must be considered the influence of *Faux-bourdon* and *Gymel* (qq. v.). As early as the 1st half of the 11th cent., however, Guido d'Arezzo in examples of organum from the Micrologus used the 3rd in the ***occursus*** (close) or coming together of the parts at the end forming the cadence—progression of 3rd to the unison. In the organum of the late 11th and early 12th cents., the 3rd was employed between consonances "in passing".

The first stage in the development of polyphony involved a note-against-note technique. Sometime prior to the 12th cent. a new procedure appeared—the practice of singing a florid melody in the upper part (***discantus***) against the sustained tones (***tenor***) of a Gregorian melody in the lower. In the development of this new art variously called ***musica mensurata, ars mensurabilis,***

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

etc., i.e., measured music, France (Abbey of St. Martial in Limoges and the school of Notre Dame de Paris), which during the 12th and 13 cents. was the intellectual center of Christendom, took the lead. The necessity for indicating the relative length of tones led at first to the adoption of the rhythmic modes (q.v.) as a means to express durational values. Later theorists among them the unknown author of *Discantus Positio Vulgaris* (c. 1230-40), Magister Lambert (13th cent.) and Franco of Cologne (2nd half of 13th cent.) devised means by which durational values could be expressed with mathematical precision. Emphasis was placed on ternary rhythm i.e. the division of durational values into threes (***tempus perfectum***), the justification for which was found in the dogma of the Holy Trinity. The much maligned duple rhythm (***tempus imperfectum***) was restricted for the most part during the 12th and 13th cents. to secular music.

Two great figures loom in the latter half of the 12th and early 13th cents., both leading lights of the great Notre Dame school at Paris who gave direction to the so-called ***Ars Antiqua*** of the 13th cent.—Leoninus (fl. 1160-80) *optimus organista,* composer of the *Magnus liber organi* consisting of a cycle of 2 part organa (*organa dupla*) for the ecclesiastical year, and Perotinus (fl. 1180-1236), *optimus discantor et melior quam Leoninus* who remodelled and added *clausulae* to Leoninus' *Magnus liber* which functioned as substitutes for certain individual sections of the organa. Practically nothing is known of the lives of these composers save for some information given by the English author of Anonymous IV (2nd half 13th cent.). Leonin substituted the rhythmic modes for Gregorian rhythms in the tenor (i.e. base in the modern sense) of his organa. Perotinus who went beyond his master, Leoninus, wrote not only 2 part organa but 3 part (*tripla*) and 4 part (*quadrupla*) organa. The employment of imitations and sturdy modal rhythms gave his polyphony a unity secured through specifically musical means independent of textual considerations.

Outstanding also among the forms practiced during the period of the Ars Antiqua are the ***conductus*** and the ***motet.*** The *conductus* was a musical setting of a Latin metrical poem in from 1 to 4 voices. It was unique in that the tenor or ***cantus firmus*** was not taken from liturgical song but was an original melody, thus enabling the composer to give free reign to his imagination. The text which was religious or secular in content was sung by all the voices. Moving in chord-like formation, with occasional melismatic passages over one syllable the individual melodic threads of the conductus adopted a more or less uniform rhythm.

The motet which originated during the first decades of the 13th cent. was derived from the old principle of the trope. In fact the first motets were really imitations of *clausulae,* the upper part being set to an independent text. The tenor (or ***pes***) upon which the entire composition was fashioned, although taken from liturgical melody, was performed on an instrument. While the tenor sustained the liturgical melody, the ***motetus*** the part directly above, sang the chief text—an elucidation of the text of the tenor (i.e. an extension of the *mot* of the tenor, hence the word motet). The triplum (from which is derived the word treble), third voice, and quadruplum, fourth voice, if present, were also set to independent texts. Originally religious in character the motet gradually absorbed secular elements. The presence of Latin and vernacular texts side by side, and secular texts often bearing no relation to each other, became commonplace. The art of writing motets was in reality an art of combination. The interplay between the rhythmic pattern of the tenor and that of the other parts frequently based on different rhythmic modes attained in many of the later motets an extraordinary complexity. An effective device sometimes met with in motets is the ***hocket*** (*hoquetus*) in which voices alternate rapidly with one another, the melody being interspersed with rests. The motet continued in vogue through the 14th cent. long after the conductus became obsolete.

Among the writers of the motet were the trouvère Adam de la Halle of the school of Arras, and Pierre de la Croix (end of 13th cent.) of Amiens who introduced fast rhythms requiring the use of the *semibrevis* for the first time.

The influence of the Notre Dame school made itself felt in Spain, Italy, as well as in England, the last country accounting for such outstanding theorists as Johannes de Garlandia, Johannes de Grocheo, and Walter Odington. These and others—Magister Lambert and Franco of Cologne, were concerned in expounding the work of the Ars Antiqua. Apparently of English origin in style and technique, however, was the celebrated Reading *Rota, Sumer is icumen in,* (c. 1240,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

scribe Fornsete) containing religious and secular texts. This remarkable composition is a canon for 4 voices over a 2 part tenor or *pes* forming a *basso ostinato,* the first of its kind. Far more advanced in the use of imitation than works of the Notre Dame school, and comparing favorably with 14th cent. French and Italian works of similar technique, the ***Summer Canon"*** stands out at an unique example of medieval polyphonic art.

The art of the 14th cent. is labelled by musicologists the *Ars Nova* after a treatise of the same name by Philippe de Vitry (1291-1361), Bishop of Meaux, and versatile counsellor to Charles IV of France, who combined diplomacy with the arts of poetry and music. A new art emerges heralding the end of the medieval outlook. For the first time the composer takes precedence over the theorist. The use of 3rds and 6ths, the prohibition of consecutive 5ths and octaves, observable tendencies treating the 4th as a disonnance, and a more expert treatment of the cadence are all features of the works of this period. Binary rhythm was favored over the ecclesiastically sanctioned ternary rhythm although the various subdivisions of durational values into threes continued to be called "perfect". The *minim* and *semiminim,* notes of small value, saw service in the prevalent musical forms. The systems of proportional notation described in the *Ars Nova* of de Vitry and in the *Pomerium* of Marchettus of Padua (14th cent.) (both written in the course of the 1st half of the cent.) although differing in details were similar in principle.

In France the Ars Nova was dominated by Guillaume de Machaut (c. 1300-77) a truly great figure. Poet, scholar, and musician, Machaut led a varied life being for many years in the service of the restless warrior King, John of Bohemia and later attached to the royal court of France. At the time of his death he was canon of Rheims. Machaut displayed far more resourcefulness as a polyphonic composer than as a trouvère. In spite of the constant employment of elaborate artifices, the clue to Machaut's music lies in his claim that the essential guide to good composition is the ear. His output mostly secular consisting of motets, rondeaux, virelais (chansons balladées), ballades, and the great 4 part Mass, supposedly composed for the coronation of Charles V in 1364, sums up the characteristics of the Ars Nova. The 3 part so-called Mass of Tournai, (1st half of 14th cent.) made up of pieces by various anonymous composers is the only polyphonic setting of the Ordinary of the Mass, antedating that of Machaut. Written in the prevailing motet style, the Mass achieves a sense of unity through the employment of certain melodic formulas in the different sections.

In the motet, secular or religious, Machaut usually confined himself to related texts in the same language. The so-called *isorhythmic* motet featured a tenor in which lengthy elaborate rhythmic patterns called ***talea*** were repeated several times. Characteristic also of Machaut's motets is the repetition of the tenor in diminution (i.e. the values of the notes are halved).

The ***ballade*** (in from 2 to 4 parts), not to be confused with the chanson balladée, consisted of 2 lines set to the same music, the 1st forming an *ouvert* and the 2nd ending in a *clos.* The 3rd line was set to independent music. Since the leading melody was in the highest voice, it is quite likely that the lower parts were instrumentally performed.

The polyphonic rondeau was equivalent in structure to the monodic rondeau of the 13th cent. By this time, however, this form was no longer used as a dance. As in the motet, the most complex polyphonic devices were frequently used—imitations and *cancrizans,* (crab-like motion) i.e. the same melody used backwards.

The majority of Machaut's virelais are monodic. Structurally the polyphonic ones were similar in form.

The greatness of Machaut overshadowed all other French composers. Jean Cuvilier, Jacques de Senleches, and F. Andrieu are minor composers whose works bear Machaut's influence. Andrieu's 4 part musical setting of a poem in ballade form by Eustache Deschamps lamenting the death of Machaut shows the great esteem in which he was held.

The extraordinary musical activity in Italy during the 14th cent. (more precisely from c. 1325-c. 1425) is in marked contrast to the apparent inertia of the preceding century. The numerous Provençal troubadours who found refuge in Italian courts after the gloomy days of the Albigensian Crusade do not seem to have produced any imitators. No music of Pietro Casella the earliest composer of madrigales, whom Dante (1265-1321) mentions in the *Purgatorio* is extant. The early formative influences of the Italian Ars Nova, therefore, are not to be sought in Italy, but in a fusion of Provencal and

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

French elements. A marked preference for the conductus style is evident in the works of Giovanni da Cascia, also known as Giovanni da Firenze, and Jacopo da Bolognia (both 1st half 14th cent.), pioneers who paved the way for later composers. By the middle of the cent., however, the Italian Ars Nova assumed distinctive features of its own. A complete elimination of the *cantus firmus* i.e. the tenor, a penchant for canon, and the transference of the most important melodic line to the highest part are the pervading traits. The Italians were far more concerned with the idiocyncrasies of the voice than their French contemporaries. Nevertheless, there was actually no distinction between vocal and instrumental music, since in performance it was customary to substitute instruments when voices were lacking. Even more than the French, Italian composers reflected in the choice of their texts the new spirit of humanism. In the use of binary rhythm, the Italians appear to have preceded the French.

The dominant forms of the Italian Ars Nova were the ***madrigal*** (***matricale***) and caccia, both of purely Italian origin, and the ***ballata.*** The madrigal is made up of 2 sections, the 1st consisting of from 1 to 4 stanzas of 3 lines set to the same music and the 2nd, the refrain or *ritornello* of 2 lines set to different music. As a rule the meter changes in the 2nd section from binary to ternary or vice versa. There was frequent use of imitation and strict canon.

The *ballata* in common with the madrigal was written in 2 or 3 parts. In both forms melismatic passages typical of the *conductus* occur frequently. In structure the ballata is equivalent to the French chanson Balladée. The absence of a text in some compositions indicates that they were performed entirely with instruments.

Although not as highly favored as the madrigal, in certain respects the most unique form of the Italian Ars Nova is the ***caccia*** (literally hunt). Originally limited to the depiction of hunting-scenes, the *caccia* later included subject matter ranging from the picturesque to the dramatic—market scenes and street cries, fishing scenes, rural scenes, etc. The realism of these onomatopoeic texts was brought into bold relief through the use of strict canon liberally interspersed with hockets. Normally the Italian *caccia* consists of 2 sections, the 1st of which is a 2 part canon supported by a free base part performed on an instrument. The French *chace* which omitted the independent base part is thought by some to have served as the model for the Italians. The origin of the *caccia,* however, is to be found in the canonic madrigal with which it has in common the use of canon and the presence of the final ritornello, and the Italian *frottola* from which it borrows the poetic element and the vivacious representation. The *ritornello* or second section of the caccia may or may not be in canonic imitation and in some instances is omitted altogether.

Besides the two already mentioned composers, among the exponents of the Italian Ars Nova are Ghiraldello da Firenze (c. 1368), Magister Piero (14th cent.), Lorenzo da Firenze (late 14th cent.), Vincenzo da Rimini (Vincenzo da Imola) (late 14th cent.), Niccolo da Perugia (late 14th cent.) and Zaccaria (papal singer 1420-32). The greatest of the Italians was the blind Florentine poet, composer and organist at San Lorenzo, Francesco Landini (1325-97) who together with Machaut dominated the century. Landini's fabulous reputation as a master of all instruments, and popularity as a composer and poet are well attested. In 1346 at Venice he was awarded the laurel crown by Pietro il Grande, king of Cyprus in the presence of Petrarch. Giovanni da Prato's *Il Paradiso degli Alberti* (1389), which contains pictures of Florentine life, gives a vivid description of the blind musician who performed his love verses so sweetly that "their hearts almost burst from their bosoms".

Over 150 compositions of Landini written in the forms practiced at the time are extant. In many instances the composer supplied his own text.

With the 15th cent. the medieval period may be said to have been concluded. The musical art of the English composer Dunstable (d. 1453) as well as his two great contemporaries of the Burgundian school, Dufay (d. 1474) and Binchois (d. 1460) though stemming from Italian and French sources is based on new methods which cannot be investigated here. These are the earliest composers whose polyphony is in a direct line with that of the great 16th cent. schools. The phenomenon of nationalism, the institution of royal choirs and chapels, and the 15th cent. Burgundian and Flemish schools which hold sway over Europe, are new forces leading to new destinations. **medium.** Any adhesive material that is capable of cementing together the grains and particles of pigments used by the painter, can be called by this name. There has been occasional confusion between the word, medium, properly used, and non-adhesive materials added for purposes of thinning a paint mixture. Technically, the latter—water with aqueous mediums or turpentine with oil, should be classed as solvents or diluents rather than as binding mediums. The word, vehicle, is a synonym of medium. See ACOUSTICS. —G.L.S.

**medium relief.** See relief sculpture.

**megaron.** See Aegean architecture.

**Megilp.** This name was given chiefly during the 19th cent. to a mixture of mastic resin and linseed oil which was added to commercially prepared oil paints during the painting process. With change in painting styles and painting methods, it has been largely abandoned. —G.L.S.

**Meldrum, school of.** The term refers to a group of Australian painters who follow the teaching and the art of the painter Duncan Max Meldrum (1875- ) who, in 1913, established the Meldrum Art School in Melbourne. In *The Invariable Truths of Depictive Art* (1917) Max Meldrum has stated what he believes to be the principles of painting. Meldrum contends that painting is "a pure science—the science of optical analysis", and he maintains that the painter has the task of translating optical impressions in terms of his medium and in the scientific order in which these impressions come to the eye; tone being first, proportion second, and colour third.

During his teaching Meldrum exerted considerable influence and met also with strong opposition so that, for a time, the artists in Melbourne are said to have been divided into the so-called Meldrumites and anti-Meldrumites—a division which, however, has ceased to exist. Some of the followers of Meldrum are: Justus Jorgensen, Colin Colahan, Percy Leason, Archibald Colquhoun, John Farmer, Olive Frick, and others. See *Max Meldrum, his Art and Views,* edited by Colin Colahan, 1917; William Moore, *The Story of Australian Art,* 1934. —H.H.

**Mesa Verde** (Span. green table land). A large mesa 15 miles long and 8 wide, in southwestern Colorado, so-called because in a generally arid land it is covered with cedar and piñon. In the cliffs of the canyons that traverse the mesa the Anasazi built hundreds of cliff houses, some of them the finest of the Great Pueblo Age. Cliff Palace, Spruce Tree House and Balcony House (the modern names were given by their discoverers) are among the most important. Cliff Palace occupies a cavern high up in a cliff wall protected from weather and enemies. It consists of about 200 round or rectangular rooms of well-laid stone and adobe with timber and adobe floors and roofs, up to four stories high, and about 20 kivas. The site is now the Mesa Verde National Park. See Pueblo art. —H.G.

**MESOPOTAMIAN ART.** Mesopotamia, i.e., the land of the two rivers Tigris and Euphrates, is a long and narrow strip of land bordered by the Arabian and Syrian deserts in the southwest and by the Zagros Mts. in the northeast. It is thus open to the invasions of the lowlanders of the desert who were of Mediterranean race and spoke Semitic languages, and of the highlanders who were of different ethnic stocks and spoke languages which were neither Semitic nor Indo-European; with the highlanders came occasionally intruders from father north. These immigrations began as soon as the country became inhabitable after the Ice Age; they influenced the history of the country in that they took place at different times and affected different parts of the country differently. Mesopotamia is thus a fertile field to study the emergence of a synthesis out of different elements. The material for such study still contains a number of gaps, yet the main lines of development can be drawn.

*The period of Preparation: Before 2900 B.C.* The beginnings of art go back into the prehistoric period, but it seems that at least southern Mesopotamia played no creative role in the earlier phases. A change took place in the first half of the 4th millenium, when Mesopotamia became the leading country of the ancient world, even surpassing Egypt. Architecture gives us a good picture of what was achieved. The temples show a surprisingly advanced and complex type and reach monumental size at the end of the period. A dual origin is discernible. The native materials of the alluvial plain are mud and reeds; the mud, shaped into bricks, became the material most frequently used; reeds used for light huts in the beginning were of secondary importance later on. Besides, there are traces of the use of wood which must have been imported from the wooded mountains by immigrants. But brick construction was soon substituted for it so that forms first created in wood survived only in decorative features, esp. in the vertical panel decoration of the surfaces of sacred buildings. The earliest rooms show two distinct types. One is the "long" room, i.e., an oblong room with the entrance in one of the short sides. We must conclude

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

from its geographical distribution outside of Mesopotamia that it was introduced from some area north of the highlands. The other type has the entrance in one of the long walls close to the corner so that the person entering must turn to get to the altar or to the cult image which is located at the far-off short side. This type originated in the lowlands, perhaps in Syria, and may be termed the "around the corner" type. Used in ordinary houses it gives privacy, cherished by the Oriental, because a passer-by can see through the door very little of the room. **Temples** consisting of a number of rooms mingle the two types, with sometimes one type, sometimes the other, dominating. Such mingling and flexibility is characteristic of the prehistoric period as well as variety and unpreciseness; integration and fixed organization is still beyond the capacity of the builders. One type, the tripartite one, deserves special mention. It consists of a long and narrow central space which is flanked by a number of rooms on the two long sides and sometimes also on one of the short sides. It is uncertain whether the central space was covered or was a court open to the sky. A certain centripetalism is noticeable in spite of the great elongation. The origin may be looked for in **private architecture.** When the highlanders left their easily defensible mountain abodes and settled in the plain, they surrounded their huts with a wall to protect their belongings from the marauding Bedouins. When more rooms became needed, they were arranged in a row along the wall with the central space left open to the sky and reserved for animals. This "court" type would thus be of native origin. It was used also for temples, because an Oriental temple is the house of the god and should be as splendid or even more splendid than that of the king. They were decorated with wall paintings and with friezes of inlaid animals; ornamental patterns were produced by sticking into the mud walls clay cones the thick ends of which were painted with different colors; there were staircases leading to the flat roof from which the sky was observed; symmetry in the arrangement of the rooms begins to appear, an interesting feature which seems to have been introduced by highlanders. Some temples were erected on terraces; the fact that these terraces are higher than the merely utilitarian purpose required, i.e., to raise them above the inundation level, would warrant the assumption that they were meant to be artificial mountains introduced by mountaineers who believed that their gods dwelled on mountain tops.

The finds of **sculpture** are still scarce. Of the earlier phases small clay figures only are known; some represent deities, others perhaps worshippers; the execution is summary; those which are represented as draped have a columnar body and prove that this type, which is the prevailing one throughout Mesopotamian history, existed from the beginning. A life-sized head in marble and a statuette of a woman in stone coming from the end of the period show that monumental sculpture and the characteristic type of Mesopotamian statuary had been created by that time. The forms are natural and correct, but general and simplified. The statuette is in strictly frontal pose; the feet are side by side; the upper arms are vertical and not separated from the body; the lower arms are placed across the body horizontally and the hands are clasped exactly in the middle of the body. A short skirt from the waist downwards is approximately bell shaped and without folds. The proportions are heavy; the forms are round, bulging and swelling. We see a thick and impenetrable mass with a smooth surface. The figure thus shows strength and vigor and reveals the spirit of the settlers: they plant themselves on the occupied ground as firmly as possible and make themselves as strong and as unassailable as a rock. Power, not grace, is their aim. The religious meaning must not be forgotten. The statuette was set up in a temple. It did not "represent" the worshipper in the modern sense, but was considered to be alive and endowed with the magic power to remind the god of the piety of the dedicator and to assure the divine blessing.

Concerning minor arts we find objects for practical use, for the cult and for personal adornment. **Pottery** was made on the wheel and had become an industry. It shows good taste, particularly when painted, and is of great historical value, because shapes and decoration reveal a synthesis of influences brought in by lowlanders and highlanders. Equally instructive are the innumerable **seals** of stone, each with a different design, because every Mesopotamian possessed one and used it for his highly developed business transactions. Two types existed: the stamp seal and the **cylinder seal**, the latter rolled over the soft clay which was used for sealing jars and for tablets on which the transactions were inscribed. The stamp seal originated outside of Mesopotamia and was not much

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

used there; the cylinder is a Mesopotamian invention. Its appropriate decoration is the **frieze**; figures and objects are lined up one behind the other, nearly all being represented in profile so that a flat and rather two-dimensional picture results. Human figures in front view are avoided except in special cases, because they were considered to have a magical influence on the beholder. Some friezes of the last phase in this period show a freer composition with the figures spread over the field on different levels. This type is best taken as a survival of primitive unpreciseness and looseness and no attempt at perspective should be read into it, because perspective presupposes a much higher development and was accomplished first by the Greeks; furthermore, other works in the minor arts as well as in architecture and in sculpture prove that the aim of the artist was to preserve the solidity of the surface and not to disrupt it by holes going into the depth as pictures in perspective do. A number of seals show **heraldic groups**. Now, heraldic groups have a closed composition and are thus fundamentally different from the frieze which is endless and runs on as far as the available field permits. We must conclude that the two principles were introduced by immigrants from two different regions, and this conclusion is borne out by the fact that the closed composition is especially popular with the Western highlanders and that the frieze is the most favored composition of the lowlanders, the latter being a part of the Mediterranean world where the frieze is dominant; e.g., in Egypt, Greece and Spain. The Mesopotamian heraldic groups are often very ingeniously incorporated into the frieze: two rampant quadrupeds facing one another are repeated several times, but instead of being isolated, a connection between the groups is effected by having the heads of the animals turned back and their tails crossed; a synthesis of the two principles is thus achieved. The motives of the seals are ornaments, animals, and human beings in various occupations, and tells us much of the culture and esp. of the religion of the period. Worth noticing are representations of scenery. Contrary to Greek classical art nature is not entirely subordinated to man, but a coordination is attempted although in a primitive manner. A "hunt in the mountain valley" shows two ranges of mountains flanking the valley; the hunters, the game and a tree are all shown on top of the higher range. The exuberant vitality and the creative power of the period is well exemplified by the vigorous style, the variety of new motives and the experimenting with techniques and materials, many of which had to be imported: clay, wood, horn, alabaster, basalt, granite, limestone, sandstone, serpentine, even paste and an artificial stone made with gypsum, shell, mother of pearl, lapis lazuli, gold, silver, copper. Often a number of materials are used: wooden figures are plated with gold; stone figures have inlay; copper wire was used for fastening; casting and soldering were known; garments were decorated with colored patterns.

*The Early Dynastic Period. Ca.* 2900-2360 *B.C.* We are now in the historical period and know that the people ruling in southern Mesopotamia were the **Sumerians**. Their ethnic relationship and their original home are unknown, except that it is probable that they came from the highlands or from beyond. They had migrated into Mesopotamia some centuries earlier, but might have been reinforced about 2900 by a new invasion. A number of great towns existed in the south; they were competitors in creating culture but also waged wars among themselves, unified empires remaining ephemeral. The culture was uniform over the whole of Mesopotamia, although further excavations may show regional differences of secondary importance. The decisive difference from the earlier period lies not so much in the creation of new motives as in a new style. The exuberant, but loose and sprawling vitality is disciplined; integration is achieved and a fixed organization is built up.

In temple architecture much variety still exists according to the needs of the individual temples; some consist of a single room only; for others a few rooms suffice; but also big complexes with dozens of rooms were built, because many temples owned large estates and were big business entreprises. Two main types are discernible, and in both the tendency to develop a strict organization can be followed step by step. One type consists of a block of rooms; the largest room is the cult room and is of the "around the corner" type; it is the organizing center and the other rooms are subordinated to it and grouped around it in various numbers and arrangements. The other type is related to the prehistoric tripartite type. Here the cult room, likewise of the "around the corner" type, is combined with a courtyard, but the courtyard is becoming the organizing center; the cult room is pushed off the center and other rooms, often likewise cult rooms, are

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

grouped around the courtyard in the middle; the arrangement is strictly centripetal because the rooms are accessible from the court and have no outside openings—probably not even windows and certainly no large ones. Furthermore, the ground plan is not elongated as before, but often comes close to a square. The walls, all of brick, were thick; the outer ones were plain except for vertical buttresses. The impression of the beholder must have been that of compactness and concentration expressing the immovable strength and power of the deity, who gives security and prosperity to the people. Some details must be mentioned: certain temples were built on a long platform, others on a higher terrace which might be surrounded by a single or a doubled enclosure wall, probably a feature introduced from the highlands; the main entrance is flanked by two towers giving a fortress-like appearance; the cult room may have an anteroom and a clerestory in some cases; walls were lavishly decorated with colored stones and metal plaques forming decorative patterns; also figure friezes were found but their location is uncertain; if they decorated the outside at all it was exceptional; exceptional were also columns and pillars; altars, ablution basins and ovens served the cult. We do not know much of civic architecture. The towns were surrounded by strong walls which had deep buttresses; the layout was irregular except for some restricted parts where a regular plan is discernible showing the streets parallel and at right angles. Private houses display the centripetal type with an organizing central space and a ring of rooms around it. Vaulting had been developed, although most of the ceilings were flat and made of palm logs with layers of matting and clay; doors were often arched; windows were rare, small and high up in the walls to secure privacy; sun dried bricks were mostly used because the lack of fuel made baked bricks too expensive for ordinary purposes; most walls seem to have been plastered.

Our knowledge of Sumerian sculpture begins unfortunately not with the first, but with the second of the three stages of the Early Dynastic period. As in architecture a fixed organization has replaced the former unpreciseness, although the general type has remained the same: the figure stands in frontal pose with the feet side by side and with the hands clasped in front of the body. But the contour is pressed into a hard and geometric scheme: the garment reaching from the waistline downwards is prevailingly cylindrical; the body above shows straight and hard lines; the head too has sharply cut forms; long beards are divided by a number of horizontal parallels. A figure seated cross-legged is cast into a conical scheme; all parts fit in consistently; the garment covering the legs has an upward curve; the upper arms are held obliquely and give the outer contour; the forearms are not horizontal but form an angle pointing to the top of the cone; even the eyes are set slightly obliquely. All forms are simple and general, not naturalistic; the contour of the skull is a simple geometric curve, not modulated as in nature; the proportions of the face are faulty; the forehead is too low; the nose and eyes are too large; the arms and legs do not show any differentiation of muscles. Compared with the marble head of the preceding period, we almost feel compelled to assume a regress in naturalism. The skirt is of dubious interpretation, whether it is a sheep skin or more likely a textile imitation of one. It has in many examples a plain surface except for a long fringe at the bottom which emphasizes the roundness of the figure.

The following stage saw an increase in naturalism and refinement. The strictly geometric shape of the body assumes more natural forms by curving in and out; the proportions of the head become closer to those of nature; the forehead is higher; the eyes are better placed in their sockets and better balanced with the cheeks; the mouth is finer; the arms show some muscles; in exceptional cases one of the legs is slightly advanced suggesting mobility. In Egypt two persons forming a group are juxtaposed, each being strictly frontal, but in Mesopotamia a unified group is achieved by slightly turning the upper parts of the bodies toward each other, by making the body of the wife slightly overlapping and by having the arm of the wife grasped by the man. Yet the forms remain massive, and in particular the garment gives the impression of a heavy and absolutely impenetrable block; numerous parallel flounces cover the whole length of the skirt forming a solid surface and illustrating the round shape of the block. Some figures coming from the south show this massivity in the extreme; they are very short and stocky figures; the neck is very short; the body is broad; the arms are not separated from it so that the compactness is increased; the garment begins above the waistline so that the body is not articulated by it into two halves as in other figures; the stone is not

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

cut away between the garment and the base. The figure appears firmly planted on the ground as an immovable mass and thus displays a parallel to the temple. Since these figures belong to the final stage of the development, their style must be intentional and cannot be attributed to incapacity; the failure to cut away of the stone around the legs and between the arms and the body cannot be due to the fear of weakening their actual stability, because the artists of the preceding stage were not afraid to do it. More finds are needed to prove or to refute the tentatively proffered hypothesis that this difference between the two styles is once more due to the ethnic dualism in Mesopotamia, at least in part, because different development stages likewise show different proportions. But it seems that the extreme compactness is not only characteristic of the third and 'intensified' stage, but has been increased by the specific style of the highlanders. The style of the lowlanders tends to more articulation and slenderness. The Egyptian style corroborates such opinion, because the Egyptians are related to the lowlanders; notice what was said about the frieze. Egyptian sculptures show greater slenderness and more articulation than Mesopotamian ones; on the other hand, they are not round, but tend to be rectangular with sharp edges. The round Mesopotamian statues thus show that a synthesis of the two ethnic elements has been achieved also in sculpture and that the two different ethnic styles have become secondary, slightly modifying the general style in some regions and in some stages of the development.

The extant reliefs are of varying quality; scenes of ritual and of war are represented. One, the *Stele of the Vultures* might be described more fully. It is divided into registers. The largest shows a god with a net in which captured enemies are held; others depict the king at the head of his attacking armies and vultures swooping down on the slain bodies; a heap of such bodies in marshy ground is shown in another scene. The variation and realistic rendering of the subject which includes elements of nature is remarkable; the army is represented as a compact phalanx by showing the men overlapping horizontally and vertically. Yet depth and three dimensionality is reduced as much as possible so that the relief appears as intentionally flattened and as showing a solid surface. The subject matter is disciplined. The forcing of life into an ornamental scheme is particularly well exhibited by the cylinder seals which show symbolic battles of heroes with animals attacked by other animals. The composition is the same synthesis of the frieze and the heraldic group as in the previous period, but all looseness has disappeared. The whole field from edge to edge is thickly filled with figures. For this purpose the animals are set upright so that they cover the same space as the heroes; two are often crossed in an S pose to present an ornamental scheme.

The minor arts flourished as before. Mention might be made of granulation, fluted and incised vessels of gold and silver, a "helmet" of gold showing ornamentalized hair, an inlaid gaming board, a lyre of inlaid wood decorated with a wooden bull's head plated with gold and wearing a beard of lapis lazuli, female adornment in the form of necklaces made of beads and wreaths of leaves and of flowers. The famous "Royal Tombs" of Ur yielded especially fine specimens, although it must be admitted that neither the workmanship is so delicate nor the taste so good as that of Egyptian work.

*The Akkadian Period. 2360-2180 B.C.* In the following period the Semites of Akkad (central Mesopotamia) became dominant and their ruler Sargon founded a universal empire. The monuments are not numerous. In architecture the former types continued. A palace shows a number of central courtyard systems lined up side by side, not incorporated into a block as formerly, but no axiality is applied as in Egypt. Good care was taken of drainage and sanitation. In sculpture a new style is discernible. Slender proportions and articulation, the characteristics of the lowland style, are dominant. A girdle divides the upper part of the body from the lower, but the roundness and blocklike appearance is retained. On the other hand, the geometric scheme is being abandoned in a rapid development and a great step toward naturalism is being taken. The bodies appear flexible and moving freely with the muscles finely rendered; the flesh looks soft; folds, although used sparsely, render the natural texture of soft stuff. A great masterpiece, the *Stele of Naramsin,* can be compared to the stele of the Vultures to point out the differences of the two styles. It likewise glorifies victory. The former division into registers has given place to unification; the dividing lines survive as undulating and ascending ledges on which soldiers among trees are climbing up a mountain; the king is ahead of them on the top of the pass; before him his enemies are descending; this triangu-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

lar arrangement excellently symbolizes the climax of the campaign; symbolic is likewise the small number of soldiers and trees; no really naturalistic stage has been reached; also the third dimension is strongly reduced; all figures seem to be in the same layer, whether they are in the lower or in the upper part. There is no foreshortening whatever; on the contrary, the king is taller than the soldiers because of his greater importance. On the other hand, the figures are not so crowded together, they are rounder and the relief is not so flat as in the preceding period.

The same greater spaciousness is seen on the seals. Some of the older ornamental types are retained, but they are taken out of the continuous chain and freely displayed. Many cult and mythological scenes are represented in a fine and delicate style; indication of scenery is restricted but not lacking.

*The Neo-Sumerian Period: ca. 2070-1960 B.C.* The empire collapsed under the invasion of mountaineers. After a while the Sumerians came to the fore again in the south, although they were now strongly mixed with Semites. The central court type was as popular as before; if more than one was needed, they were lined up in a row or comprised in a square. The Mausoleum of the kings of Ur has cult rooms around a central court and underground vaulted burial chambers. An increase in symmetrical arrangement is discernible: the "around the corner" room has been changed into the "broad" room in which the throne or the cult image is located in the middle of the long side and is in the axis of the entrance opposite to it; it could thus be seen from the court yard; ostentation has replaced privacy. The simple and high terrace of a special type of temple has become by now articulated by stories; it is called mountain peak—**ziggurat**. The number of stories varies; their reduction in size toward the top is considerable; they are painted with different symbolic colors; the plan is oblong, later square; of three large staircases one is put vertical to the long side, the two others parallel, all meeting in the center. The striving of the Mesopotamians for massivity and solidity could find no better expression than these bulky and powerful landmarks visible from afar.

The sculptural type still shows frontality, the feet side by side and the hands clasped; the solidity and roundness are likewise the same as before; the shortness and compactness are even increased beyond that of the Akkadian period and reach the exaggeration of the last stage of the Early Dynastic period, at least in the earlier phase. It is clearly a reversion to the highland style. On the other hand, the dress has been changed for mortals, although the garment with many flounces has been retained for the gods, an interestingly archaizing tendency for it indicates a lessening of the creative power. Men wear a mantle wrapped around the body, over the left shoulder and under the right arm; it has a short fringe forming a decorative pattern; a long line falls from the left wrist to the edge of the mantle which ends above the ankles; this line without being in the center of the body indicates the vertical dimension of the body; two horizontal lines branch at the ends, one along the lower edge of the mantle, the other produced by the upper contour of the left arm; the right arm likewise provides an almost horizontal line going in the opposite direction. An articulating frame of lines is thus produced which, however, remains on the surface of the body and leaves the compactness unaltered. We can hardly be wrong if we attribute this articulating tendency to the lowland style and see in this combination of articulation and compactness once more a successful synthesis. The style is very refined, for the mantle has large, smooth and finely polished surfaces and the fringes are delicately carved, while some small and rather ornamental folds and finely incised inscriptions enliven specific parts of the statue. The head is extremely well modelled and shows accurate and natural proportions; all its forms are conspicuously round. After a while the style became extremely hard and petrified and mannerism began, a frequent stage of development.

*The Babylonian Period in central and southern Mesopotamia. Beginning of the second millenium to the Persian conquest in 539 B.C.* Scarcity of monuments forces us to deal with this long period as one unit. This does not exclude a number of fluctuations in the stylistic development; moreover, the political development was full of vicissitudes and the country often under foreign rule. We are further justified by the fact that the creation of types was achieved before this time and that now only elaboration and refinement were advanced. We can term this period neo-classic and in retrospect the Early Dynastic period archaic, the Akkadian period balanced or classic and the Neo-Sumerian period intensified. The long room is used again in the second millenium; it is impos-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

sible to tell at present, whether intermediate examples will be found in the future, or whether it was reintroduced. The town of Babylon was laid out according to a scheme which showed a network of parallel streets crossing at right angles; since, however, neither completeness nor preciseness was needed or intended in the Orient, it fell short of the regularity of the Greco-Roman or modern type; moreover, in the course of time it became increasingly irregular, because many owners encroached upon the streets in a time of weak governmental control. Great building activity took place in Babylon in the last period before the Persian conquest. Enormous walls—considered one of the seven wonders of the world—surrounded this largest city of the Ancient Orient. The strongest gateway, the Ishtar Gate, and the walls of a large avenue leading to it were decorated with faïence tiles showing lions, bulls and dragons on a blue background and must have made a dazzling effect on the traveller coming from the gray and dusty plain. A straight and paved street led to the gigantic complex of the sanctuary of Bel; it consisted of a precinct which was surrounded by large caravanserais for the pilgrims and it contained the large temple and the famous tower of Babel, ca. 270 ft. square and high. The temples of that time were rather uniform in plan, all being built according to the central courtyard type with a broad cella and anteroom. The houses were of similar type and had broad reception rooms; a number were probably more than one story high. Other monumental buildings were the palaces of Nebuchadnezzar. One of them consisted of five courtyard systems which were placed side by side, but not lined upon an axis. Each contained a large courtyard in the center with a large room on one side and numerous smaller courtyards surrounded by rooms filling the rest of the space. Three courtyards were occupied by the administration, the two others belonged to the king and the queen. The throne room was a broad room with three entrances of which the central one was larger than the flanking ones; the façade was decorated with colored faïence tiles showing lions, schematized palms and ornaments; it was 51 x 156 ft. in size and perhaps had a longitudinal barrel vault. In one corner of the palace a complex of numerous vaulted rooms was found; they were built of stone, whereas all the other rooms were built of bricks; since some had wells, the excavators interpreted this complex as the substructure of the famous hanging gardens.

The style of sculpture is fine and natural, but lacks vigor and strength. Large and smooth planes and delicate lines produce the appearance of elegance and technical perfection. The articulating framework of lines on the surface of the compact block is popular. The most elaborate scheme appears on a relief of the end of the second millenium. A king is clad in an embroidered garment reaching from the neck to the feet; a belt gives a strong horizontal articulation; two bands crossing from the shoulders to the hips form diagonal lines on the upper part of the body; the two arms bent at the elbows form lines parallel to these bands as does an ornamental band hanging down obliquely from the belt, whereas other ornamental stripes are parallel to the horizontal belt.

*Assyrian art from the beginning of the second millenium to the end of the empire in 608 B.C.* Before 2000 Assyrian art shows the same style as the art of the south except that at times it has a provincial touch. After 2000 it has a style of its own which is, however, in close connection with the south and which must therefore be considered as Mesopotamian in the comprehensive sense of the word. The popular central court type differs slightly from that in the south. Here in the south it is very regular in outline, i.e., if possible, a rectangle. The palace of Sargon II in Khorsabad which combines numerous courtyards is sprawling and has an irregular perimeter with many projections. Many courtyards are more spacious than is normal in the south. Besides the courtyard type the block type, i.e., small rooms around a large covered room, plays a great role. It is used for many temples and, in Nuzi in upper Mesopotamia, also for private houses. Some Assyrian private houses show an interesting combination: the reception room occupies on side of a forecourt and the adjacent "harem" is of the central court type. The broad room occurs, but is much rarer than in the rest of Mesopotamia. The "around the corner" type is very common in temples, houses, and is even used for throne rooms. Also the long room is often found in temples, but it is incorporated into the central courtyard type. The main part of these temples is commonly tripartite; it consists of a small anteroom and a small holy of holies divided by a large long room. Notice the same plan in the temple at Jerusalem. The appearance was one of strength and solidity

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

as everywhere in Mesopotamia, although perhaps somewhat more softened by the use of decorative features. The walls of the rooms—at least of the palaces—were lavishly decorated with reliefs and paintings, but also some of the exterior, particularly the gateways had decoration, the latter having as guards lions and bulls with human heads and wings. Assyrian art shares these features with the arts farther west, as Assyrian kings also erected some buildings in the western style. Awnings, rugs and fine furniture decorated with figures and ivory, the latter likewise often of western origin, completed the splendor of the rooms. The extensive fortifications, irrigation works and one aqueduct across a valley, as well as formal gardens with parallel rows of trees, might be mentioned.

Of sculpture in the round only a few in stone are preserved; the cult images in precious materials are lost. They show frontality, compactness and solidity as do the figures in the South with an additional expression of fierceness and brutality. The Assyrians decided not only to preserve their own native ground, but also to rule; or, if necessary, to exterminate other nations. Often, although not always a framework of lines is marked on the surface of the block. The waistline is often slightly reduced and divides the upper part of the body from the lower one. The muscles and sinews are exaggerated and schematized. There is more variation in types than in the south and some western features appear. The body in section is not always round but also angular or flattened. In addition to the pose with clasped hands those with both forearms stretched forward and with one arm hanging down by the side and the other placed horizontally across the body are found. The garment reaches to the ground in upright figures and gives them a firm stand; it sometimes clings to the body so closely that the modelling underneath is shown; fringes around the body are fashionable.

After 2000 a strong and vigorous style is discernible; all forms are solidly modelled and sharply marked. In the second part of the second millenium a finer and more elegant style is current; even some schematization and mannerism is found but, on the other hand, a soft and delicate naturalism appears. There follows a consolidation again displaying heavier forms. The style of Assur-nasir-apli (9th cent.) shows a certain balance between the hardness and forcefulness of the main forms and the finesse and wealth of secondary detail. A gradual softening and refinement takes place until under Assur-bani-apli (7th cent.) a rich style is achieved. The figures are a little plump and well rounded; the contours are gently curved; the faces are fleshy and full; hair and beard are extremely well dressed, a feature which is found throughout the first millenium; the royal garments are lavishly embroidered.

The glory of Assyrian art is the relief. Cult scenes showing demons, etc., are in the minority in comparison with military scenes. The king is represented again and again but not as the sole victor of overwhelming height and strength as in Egypt. The whole army is rendered in great detail toiling and accomplishing all phases of their victorious campaigns. We see the footwolk, the horsemen, the war chariots; the crossing of mountains and rivers; the battles in the plains, in the mountains, in the marshes; the sieges of cities by means of beleaguering machines; their capturing, looting and burning; the torturing, impaling and abduction of prisoners; the resting in camps and the sacrificing by the king; his hunting which was not only a pleasure, often a dangerous one, but also a duty to rid the country of the beasts of prey. The rendering is realistic. We get a good knowledge of the equipment of the army, of the different species of trees and the characteristic types of buildings in foreign countries; the dying lion and lioness are famous for their lifelike representation. Natural scenery plays a much greater role than in Egyptian and classical Greek art. This characteristically Mesopotamian feature which we noticed in the earlier periods was brought to its fullest development by late Assyrian art. Great unified pictures show the human figures placed on a background of landscape, certainly not in the real proportion to it, but not so magnified and much better inserted than in foreign arts. Moreover, these pictures are isolated spots of a larger composition which consists of a number of superimposed friezes, each having the height of one figure only and becoming unified if the particular subject matter demands it. Occasional heraldic groups are likewise subordinated to the frieze composition which often goes all around the four walls of a room without being interrupted at the corners. The principle of roundness and concentration rules here, too, as in sculpture and architecture, and gives the room the appearance of a complete unit instead of con-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

sisting of four separate walls put together. The desire to keep the solid appearance of the wall, as well as the Assyrian mentality as such, prevented the artists from developing perspective. There is no foreshortening, no three-quarter view, very little overlapping. If some figures are smaller, this is due to lack of space as is clearly shown by the fact that smaller figures are introduced in the foreground; the beholder does not get the impression that figures or objects in the higher part of the relief are at a greater distance, but all, whether they are above or below, appear to be in the same vertical layer; i.e., on the surface of the solid wall. This fact as well as the frontality of the statue and the compactness of the buildings, prove that Mesopotamian art always remained "archaic" art and never reached the classical style of development. See various publications of the Oriental Institute of the University of Chicago; publications of the British Museum on Assyrian art; publications of the German Oriental Society on excavations; Musée du Louvre, *Les Antiquités Orientales* by G. Contenau; G. Contenau, *Manuel d'archéologie Orientale,* 1927-31; H. Frankfort, *Cylinder Seals,* 1939. —V.M.

**metal.** See GLASS AND GLASS-MAKING.

**metalwork.** The art of metalwork has had a continuous history since the Bronze Age. The alloy of copper and tin or bronze has survived in the form of sculpture, arms, utensils, and furniture. Iron was widely used for architectural embellishment in the Middle Ages and the Renaissance and is being revived in modern times with a new understanding of its ductile properties. Copper and zinc, or brass, was exploited by the Romans and notably in medieval England in architectural forms. Gold and silver work, with its close relationship to jewelry-design, has been in continuous development.

The basic methods of preparing metals for craft uses have been drawing, spinning, hammering, and casting. Stamping, inlaying, damascening with threads of gold or silver, niello-work or metallic inlay on engraved gold, silver, or bronze, and repoussé work, the design being beaten from within to form a raised pattern, are more intricate techniques. The alloys, brass and bronze, and the precious metals, gold and silver, have the longest history of experiment and expression.

The characteristic method of using bronze is that of casting, the **cire perdue process** being the one favored from ancient times. In this process a fireproof core is covered with a modelled wax figure which corresponds exactly to the finished work desired. A mould s then applied connected with the core by metal rods. Molten bronze is then poured n replacing the wax, which melts and runs out. When the mould and core and metal ·ods are removed, and the surface tooled, the wax object reappears in bronze plate. The story of the achievement of artists in this craft is a long and distinguished one, and clearly raises questions of where craft ends and art begins. In the classical world, copper appears as early as 3500 B.C., but the bronze alloy is not widely current in Crete until 2000 B.C. Weapons and metallic pottery forms are the sole relics of the Copper Age, revealing evidences of Egyptian and Mesopotamia influence. From the late Minoan Age the bronze dagger blade found in a Mycenaean shaft grave, with a floral design running the length of the shaft in gold and niello, is representative of the expert craftsmanship in arms. Bronze work in utensils and statuettes were less notable. Italian and Oriental motives and techniques as well as survivals from pre-Hellenic times appear as the Classical Age reaches maturity. Tripods and bowls, mirrors and chariots are produced in cast and plated forms with decorative motifs used to cover structural joints, embellish rims, and serve as pedestals and bases. Human beings, plant forms, and mythological conceits are the motifs commonly employed. The Pourtales Vase in the British Museum with a human figure for the handle and silver inlay enrichment is an example. Etruscan bronze work, a provincial phase of the Greek, specialized in line engraving, as seen in the Dioscuri Mirror in the Metropolitan Museum. In the notable Monteleone chariot in the same museum, enriched by repousse, a monumental adornment of functional forms was achieved. In late Greek and Roman times bronze furniture forms embellished with conventionalized flora and fauna forms were characteristic, and statuettes might repeat famed works of masters of sculpture.

The Roman works of bronze for architectural and domestic purposes carried into medieval times. The bronze doors of the Baths of Caracalla reappeared in the Lateran Church in Rome, and a Roman curule chair with 12th cent. additions was rechristened the Chair of Dagobert. During the first

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Golden Age Byzantium was the trade center for widespread traffic in bronze ware. After the Iconoclastic controversy at least technical knowledge survived and the bronze doors of Romanesque Italy were of Greek origin or of Greek workmanship on Italian soil or of Greek inspiration, combined with neo-classical tendencies. Greek refugees of the 9th cent. were welcomed by Charlemagne at Cologne and at Aix-la-Chapelle. The bronze doors at Hildesheim and Mainz and Augsburg are noteworthy for introducing Teutonic art forms, as seen in the lion heads with rings hanging from their jaws. Candlesticks, baptismal fonts, and candelabra add further examples to the rich medieval pageant of bronzeware in German lands. Perhaps Peter Vischer in Nuremberg in the Shrine of St. Sebald achieved the ultimate embellishment of a monumental form, mingling medieval and Renaissance detail. In the Tomb of Maximilian I at Innsbruck he showed equal skill as a monumental sculptor.

The Renaissance in Italy achieved great bronze monuments from the Andrea Pisano doors at the Baptistery in Florence to Ghiberti's first and second pairs, in the last blurring not only the distinction between craftsmanship and art, but even between painting and sculpture, so subtle are the plane relationships, so fluent the form, and precise the line. While all the great sculptors of the Italian Renaissance used bronze as eagerly as the Greeks had, usually preferring its sheen and clarity to marble ambiguity, the story is continued along craft lines rather than creative ones when the Venetians commission door knockers or Rovezzano carries Renaissance forms to England in the Cardinal Wolseley tomb.

Bronze work in medieval France has largely gone, save for such supposititious examples as the base of the seven-branched candlestick in the Cathedral at Milan. With the Renaissance the development of ormolu, or gilt bronze, for the adornment of furniture, as well as the quasi-monumentality of Goujon and Pilon with their interest in decorative emphases, indicates how serious has been the loss of medieval French work in bronze. Furniture in rococo forms reached heights of amazing elegance, saved from overlavishness only by the soundness of craftsmanship and the native French taste. Not a few ecclesiastical objects of medieval England are extant, marked by sobriety and technical soundness, a restraint which controls Gothic grace and helps fuse medieval and Renaissance decorative motifs in later times. An intriguing bypath is that of bell-founding where the ponderous tone is on occasion integrated with the weight of the metal and the sobriety of the profile.

European brass as distinguished from bronze has a more distinctly ornamental appeal. Its value is largely one of embellishment, aided by its brilliant color. From medieval days cast and repoussé techniques were followed in brassware, the output of Dinant being especially popular throughout western Europe, called *"dinanderie"*. Ecclesiastical objects in this technique include such masterpieces as the font in St. Bartholomew's in Liege, and the lecterns in the English churches. Cologne was also a notable center. Symbolic figures, architectural tracery, and flat ornamentation were used richly and effectively. In the Renaissance the great chandeliers of England, Holland, and Scandanavia, the hammered work and dishes embossed with figures from Dutch craftsmen are also notable examples of brassware. Domestic utensils in brass or with brass ornament were likewise common, perhaps a water vessel in animal form with the spout extending from its mouth, and another animal form for handle. Inlay enamel designs and intricate open work, both floral and faunal in derivation, and elaborate engraving appear in the 17th and 18th centuries.

As one moves away from the European world, one finds notable and strange forms and techniques in bronze and brass. From the Near and Middle East come a bronze bowl from Nineveh, now in the British Museum, with repoussé concentric designs of animals, and the Luristan bronzes of western Iran, Scytho-Persian in origin, where animal forms are used with fluency and decorative skill. These small objects pertain to personal adornment and the needs of a horse-riding people. Of purer form is the work being recovered by the nomad peoples of north Eurasia, basically faunal in its motifs and possessing many affinities with the art of the ancient East, Sumerian and Iranian. The emphasis is always decorative rather than naturalistic. These dress accessories, arms, and horse fittings are often in gold, but also in bronze, and even in bone and wood.

In the Far East Chinese bronzes are clearly a major art, having the intricate iconography and freedom of design which underlies such a classification. Basically, they are ceremonial in purpose, and closely connected with the Chinese feeling for fam-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

ily and ancestor. The long inscriptions with their calligraphic decorative properties, suggest a relationship to meaning and writing which is strange but suggestive to the Occidental spectator. The *cire-perdue* process was used expertly from early times, whence come the finest of the bronzes. The vigor and dignity of the forms, the vital and unified outline, and the integration of form and mass give them a unique force. The artist was not afraid of angular shapes of weighted masses. The idea as well as the appearance could carry them. With meander bands to suggest natural elements, like thunder and lightning, triangular patterns to connote mountains, and tapering forms for the winds, the artist could serve a purpose functionally with his pattern, and decorate with poetic allusions. Sacrificial jars and libation cups, at times covered, of gilt-bronze or copper inlay, ceremonial tripods, and animal forms grand in scale rather than in size occur. Chinese bronzes are a continual inspiration to the sensitive spectator. Pantheism, continuity, vitality are given permanent form, enriched by the patina of centuries of burial or exposure to atmosphere.

Copper, brass, and bronze are widely employed in India, whose inhabitants prefer the first for images, at times gilded or even inlaid with gems, cast solid or on a fireproof core. In utensils many types of water vessels with long spouts, for religious or domestic use, are found cast by the *cire-perdue* process. Temple bells, hanging-lamps, and vases also reach high favor. Chasing, engraving, inlaying are the decorative techniques employed and the material varies from copper to bronze to brass, as the alloy consistency changes. Brass inlaid with silver and copper, copper with silver applied, brassware with engraving against a background of colored lac are skillful and sightly products. *"Bidri"* ware, of tin or zinc combined with lead and copper, is engraved and enriched with silver inlay. Polishing and darkening of the surface and conservative geometrical and floral motifs provide a choice example of minor art.

In Africa advanced knowledge of metal casting was brought to the peoples of Benin by the Portuguese; they produced noteworthy ancestor portraits surmounted by elephant tusks for use as altarpieces. The feeling for material and the sensitivity to sculptural values which marks so much of African art in materials easier to work are also seen here. A portrait of a *King* now in the University Museum, Philadelphia, is an example.

The uses of bronze in contemporary art are many, as seen in the sculptural forms of Lachaise and Epstein and Kolbe or the decorative influences of Manship and Diedrich and the precious quality of Archipenko's silvered bronzes. More distinctively designed as a minor art are the cooking utensils in copper, now clearly fashioned to serve their purpose, and the ornamental gates of bronze. Brass in minor art forms is at present less favored than in days of brass chandeliers and bedsteads. Only copper seems to have continued tradition by fresh experimentation.

The uses in the crafts of gold and silver are again long-lived and notable. In the Old Kingdom in Egypt all the fundamental ways of handling gold had been developed, casting, chasing, soldering, hammering, and plaiting. A bracelet of gold and turquoise and amethyst devised with a lotus rosette as the central motive, or a masterful hawk's head in hammered gold with jasper eyes, detached from its original position in a bronze body, are examples. Nor can one omit mention of the ceremonial vase where a gold surface is inlaid with lapis lazuli and both contour and surface decoration are kept within restrained limits. The rich profusion of techniques and lavishness of effect in later Egyptian times is suggested by the cedar wood chair decorated with embossed gold and ivory claws from Tutankhamen's tomb, or the royal effigies of gold over wood inlaid with glass, faience, and lapis lazuli. Silver was less commonly used, but a wine jug in that material, engraved and with a handle in the form of a hind and a rim of gold is a surviving example.

The Sumerians were likewise masters of gold and silversmithy. A gold cup of simple flaring profile and fluted sides, a gold helmet with repoussé and engraved adornment, and a fantastic harp of gold and lapis lazuli with bull head base are all amazing in inventiveness and technical skill.

The Minoans may well exhibit the Vaphio Cups as their example. The smooth inner lining, the turned over rim, and the riveted handles, as well as the repoussé bands of humanistic art, the taming of the bull by man, provide a perfect example of art crossing the Hellespont in its westward migration. Perhaps the gold and silver electrum coins of the Greeks, where commercial needs and feeling for sculpture in the round fight a long battle with restrained design, illustrate the best work in these materials. One feels with them as with us a distinction between major

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

and minor arts. The goldsmith and silversmith work found at Pompeii, at Hildesheim, and at Boscoreale show the Romans as lovers of elegance rather than of workmanship. And one must recall before leaving the ancient world that the Eurasian animal art is basically an art of gold with patterns worked out in terms of animal forms.

The cloisonné work of the Byzantine people, with thin gold strips forming the cells and gold for background and with enamel filling, carries this technique to a new level of achievement. With the mosaics, ivories, and textiles it suggests a culture where the minor arts have replaced the major.

The book covers of the early medieval peoples are rich in ivory, enamels and stone, as well as with gold and silver; their ecclesiastical chalices and plates are at the same time barbaric and decorative, with Celtic, Teutonic and Gallic individuality appearing now and again. In Gothic times greater elegance occurs but still the sensuous appeals of color and sheen are exploited, as in the gorgeous Chalice of St. Remi, of gold, enamel, and gems. Benvenuto Cellini's ebullient craftsmanship, to the exclusion of taste, in his famous salt-cellar in gold and enamel, and the lavish gold and silver *custodia* for the monstrance enriched with Spanish exuberance, suggest the dangerous limits approached in the Renaissance. In fact, the **plateresque** style in architecture with its popularity in Spain and the transatlantic lands under Spanish control is basically a silversmith's decorative creation.

In pre-Columbian America the craft of metallurgy was developed in Peru by the Incas and their predecessors, the folk of Tiahuanaca, and in Mexico by the Aztecs, and their predecessors, the Mixtecs and Toltecs. Notable examples of the craft in gold and silver have survived. Using all the techniques they fashioned personal ornaments as well as ritual objects. Animal and human figures were also fashioned. Jewelry from tombs at Mt. Alban in Oaxaco, Mexico, reveal extraordinary finesse.

The long story of silverware as a household utensil cannot be more than touched upon here. Its cleanness of surface and outline, its easy adaptability to varied forms, and its permanence in solid or plated form account for its wide popularity. Of especial note is **Sheffield plate** where a silver surface is applied by heavy pressure to a copper or alloy base and which provides metal which has beauty equal to that of sterling, or standard, silver, and durability superior to plated ware. In early Republican America the silverwork of Paul Revere achieved a grace and functional sobriety which while rococo and regency in derivation has also the direct craftsmanship and the Chinese echoes of the colonist and wide-awake creator. In modern times the same trend toward simplification noted in the other utensil arts has been noted in silverware. Following a "craft" period, where hammered silver was in vogue, the clean, undecorated surfaces, forms based directly on use, and the omission of bevelling, or repoussé detail which are difficult to maintain in their original brilliance, have much to recommend them. The Jensen designs, originating in Denmark, have further reached into new creative fields, and suggest that the silversmith has only to exploit his material, his tools, his purpose, to reach old, yet new, achievements.

Ironwork demands seperate treatment. Its structural uses are so varied and its prevalence so widespread that our age has been named the Iron Age as distinct from the preceding Bronze and Stone Ages. When it is recalled that iron is basic in steel, that reinforced concrete is dependent on iron or steel skeleton, the wonder is rather that iron as an art medium still survives. Yet from the days of the Egyptians to those of the elevator door wrought iron and cast iron have provided civilized man with a major part of his tools, his weapons, and his utensils. It has also provided him with decorative arts and crafts. Wrought iron with its fiber-like consistency can be hammered, drawn, or twisted and still maintain its strength. By welding parts may be completely fused. Even in a cold state iron is soft enough to be hammered and bent. Cast iron, in its moulded form, is too brittle for further manipulation, but lends itself freely to the details of the mould.

It is chiefly from medieval times that wrought iron has been developed as a medium of artistic expression. By collaring, or attaching separate units with strips, by riveting, bolting, threading, and mortising the handicraft could function widely within the limits of the exacting material. Pure form has been the fundamental element in wrought iron design, in hinges, grilles, gates, balconies, and so on. In England ironsmithy developed from the bar which gave structural force to the windows and the door hinges and to the devices made for the protection of caskets in the form of grilles and screens. Later

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

in the period the attempt was made to produce in iron stone tracery with small pieces rivetted and chiselled on a sheet background; for example, the grille over the tomb of Edward IV in St. George's Chapel, Windsor, the work of John Tresilian. The hinges of the west door of Notre Dame in Paris illustrate the controlled elaboration and grace of the medieval French craftsman.

In the Renaissance the quatre-foil grilles and lanterns for the corners of city palaces indicate the uses made by the Italian of iron. The German craftsman also in cathedral accessories and locks and chests was seldom able to pose problems he was unable to solve. In Renaissance Spain iron had a revival, notably, in the monumental screens in the churches, with vertical columns of hammered work and horizontal bands of arabesque ornamentation, the whole crowned by elaborate crests. Color and gilding produce striking effects in the dim interiors. In many cases two such screens are found in a single church, one to emphasize the altar, the other to mark the eastern end of the choir. Iron was also used for such church furniture as pulpits, and, often, with notable results, in domestic architecture, as, for example, in the nail-heads. Renaissance France remained conservative in its iron-mongery until Louis XIV, with locks, knockers, and caskets, of great skill rather than originality.

With the reign of Louis XIV, however, the era of iron's greatest development arose. Great gates for parks, mansion staircases, screens for churches were produced by a succession of artist-craftsmen, as balusters yielded to scrolls without sacrificing structural clarity. St. Cloud, Fontainebleau, Chantilly, and Versailles offer notable illustrations. In the 18th cent. rococo forms remained within the possibilities of ironwork. Lamour in the gates at Nancy perhaps reached the limits of the craft as a monumental technique. Jean Tijon at Hampton Court palace carried the French manner to England, influencing but not dominating the native craftsmen. Not only for the city houses and country manors, but also in the English resident colleges there is revealed during the 17th and 18th cents. much work of admirable simplicity and feeling for material. Germany in the Renaissance did everything with iron which the ingenuity of the craftsman could devise, at times losing structural control. The manipulation of iron bars with floral or capital ends, door-knockers, and chests with elaborate iron mountings recall the tireless energy of the south German worker.

Cast-iron was long in use in England for fire-dogs and firebacks, and the railing of St. Paul's cathedral, London, was an early example of its architectural use. In America the porches of Charleston and New Orleans, and even the entire façades, with classical detail on occasion, of business buildings, foretelling the skeleton structure of the end of the 19th cent., are further examples of architectural ironwork. This facility in the pre-fabrication of standardized ornament is now replaced by brass, and the more imaginative and native possibilities of wrought iron have reclaimed the field.

In the Middle East iron has had a long history, steel preceding it strangely enough in medieval India. Iron pillars illustrate its structural use, damascening its decorative use. In China iron has been used since 500 B.C., rapidly replacing bronze for weapons and domestic utensils. From the 9th cent. it even tended to replace bronze for sculpture. Iron pagodas and temple furniture and even iron pictures were ingenuously devised. More sensitive to the individuality of the material as a medium, the medieval Japanese craftsman in the decoration of armour, and most notably, in the embellishment of sword handles reached one of the high points in the craftsmanship of iron.

In recent times in Europe there has been a revival in the use of wrought iron. Beginning with a revival of traditional methods as seen in the Chantilly balustrade by the Moreau brothers, the modern movement progressed with Emile Robert's efforts at simplification and Edgar Brandt's efforts to combine the needs of art and of industry. While one can see the passing influence of Art Nouveau, of the Viennese Secession, and of the decorative art forms of 1925 in the output, and, let us admit, the functional abstraction of the modernist, still in our own day the art seems to have passed the dangerous period of revival, and to be ready to develop its own expressiveness neither medieval nor rococo. Samuel Yellin in America has done notable work in the field of architectural decoration and domestic furnishing, and Hans Panzer in Germany has produced such a work as the grille for a church near Munich which fairly cuts with metallic sharpness and stimulates with abstract symbolism. Stainless steel cutlery and simply designed tumblers in steel, as well as machine-made ironwork suggest further the wide possibilities in a material as

**metope.** The panel between triglyphs in a Doric frieze, usually decorated during the 5th cent. B.C. with sculptured figures, but sometimes with a rosette or shield, or left blank. How to fill this nearly square space so as to make it harmonize with the lines of the building and provide interesting surface modulation was a problem which appealed to many of the leading Greek sculptors. In the Athenian Treasury at Delphi, brisk figures were placed in dynamic diagonal, triangular and curvilinear designs; the metopes decorating the Temple of Zeus at Olympia were conceived in broader and quieter terms, with horizontal and vertical masses predominating; on the Parthenon the figures of the metopes assumed a rich variety of geometric patterns, with drapery skillfully used to bind them into a unified whole. The background of the metopes was frequently painted blue, and details on the figures were picked out in red and gold, so as to make the marble forms stand out more effectively in the bright sunlight, which would otherwise flatten them against the background. The most popular subjects were the labors of Heracles and Theseus, and the battles of gods against giants, Greeks against Amazons, and Lapiths against Centaurs. After the 5th cent. B.C., there was no metope sculpture of importance. —W.R.A.

**Mexican art, ancient.** The ancient art of Mexico and Middle America should be considered as a unit. In this region the early stages of primitive experiment and the transition from a hunting people to the beginning of agriculture have not yet been recovered by archaeologists. Three major phases may be distinguished: (a) small village period with rudimentary art; (b) ceremonial period where each tribal unit had a distinctive art style; and (c) the final period where ceremonial elements from central Mexico tended to break down the old regional arts.

Sculpture was confined at first to small baked clay figures, usually female, and while the general effect was crude there was considerable experiment and regional stylization. This type of art and type of life persisted up to the Conquest in outlying parts of Mexico with improvement in technique and presentation. The ceremonial art apparently took its first steps in southeastern Vera Cruz. Several distinctive features characterize this ritualistic civilization: erection of altars and altar temples on the mounds; polytheism and the ritualistic definition of divinities; the invention of a method of pictographic or hieroglyphic writing; the use of a calendar to conduct more accurately native worship. These steps seem to have been taken in several localities and in each case involved a distinctive regional style indubitably linked by transitional forms to the older Middle Cultures. The most important of these are the La Venta culture (formerly known as Olmec) in southeastern Vera Cruz; the Maya, visible in local traditions like those at Copan, the Peten area, and the highlands; the Zapotec tradition, best seen in the sequences at Monte Alban; and the Mexican sequence to be studied in the environs of Mexico City and in the State of Puebla. Further excavation will bring more of these to the fore. There was some change in each of these regional developments and some

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

mutual interchange of elements through trade and borrowing.

About the 11th cent. a new religion based on the old and with a distinctive ritualistic definition came into being. It seems to have been spread by conquered and migrating groups often speaking Nahuatl, the Aztec language. In the Maya country one finds this impact at Chichen Itza, Peten, and the highlands of Guatemala, and influences are detected in tribes as far south as Nicaragua. In Oaxaca the old Zapotec religious culture is transformed by this Nahua influence. In the Valley of Mexico the old civilization of Teotihuacan is replaced by two major intrusions bringing in the Mixteca-Puebla cultures and lasting to the final Aztec period. To the north the effect of both of these cultures was felt in Sonora and Sinaloa, on the tribes in the Huaxteca in northern Vera Cruz, and attenuated influences affected perhaps the Mound Builders of the southeastern United States.

The general picture of Middle American art history discloses not a gradual ascent culminating in a high artistic peak, but rather a series of plateaus where given styles persist unchanged for a very long time. These are broken, perhaps by sharp transitions, and take off again on another protracted level.

The incredibly beautiful small stone sculptures of Vera Cruz are too little studied as yet to make any affirmation as to the effects of central Mexican influences. In Oaxaca the Mexican period seems to have added to rather than detracted from the earlier art. In the Maya area there was a strong local development characterized by a strong architectural development during and just prior to the period of Mexican contact.

Middle American sculpture, particularly in clay and stone, is one of the high points of American art. Although created with a Neolithic technical equipment, the range of style and expression was comparable to that in many of the Old World cultures. In studying the development of the arts from given regions in Middle America, one is conscious of a growing mastery of the mediums involved.

There is an Oriental tinge to some Middle American art, but its distribution in terms of time and space suggests that the Oriental aspects derive from the local sculptor's ability to reproduce the features of his own Mongoloid stock rather than from direct artistic affinities. —G.C.V.

**Mexican painting, contemporary.** Contemporary Mexican painting is distinguished from other contemporary art movements in Europe and America by the unique combination of native subject matter, modern forms of expression, and functional integration with the cultural program of a national government. The origin of the style is found in the social, economic, political, and cultural reorientation which took place during the Mexican Revolution of 1910-20. Its subsequent development has been closely allied with the various policies toward national autonomy and international cooperation that have characterized the Mexican government since that time.

The first, formative, period might be considered the ten years between the great Exposition of Mexican Painting held in Mexico City in 1910 and the inauguration of a national art program under the Ministry of Education in 1920. In direct opposition to the prevailing European taste of the Diaz regime, this centennial exposition, largely organized by the dynamic Dr. Atl, featured Mexican art and subject matter as its tribute to the 100th anniversary of Mexico's independence.

Modern art in the European sense as a distinctive style was introduced under the revolutionary government by Alfredo Ramos Martínez in 1913, a Mexican impressionist who had been living in Paris, and who became director of the academy in 1913. Its introduction to Mexico was, therefore, exactly contemporaneous with the arrival of modern art in the United States via the Armory Show in New York. During the chaotic years of 1914-16 many of the artists and students of the academy, including Dr. Atl, Orozco, Siquieros, Goitia, and others, were engaged in propaganda activities for the Carranza forces. With the political stabilization of the country under President Obregon, a vast program for the cultural rehabilitation of the country was inaugurated by the new Minister of Education, José Vasconcelos. The employment of artists to paint Mexican subjects on the walls of public buildings was one of the most prominent features of that program.

The crystallization of the new style can be followed in the murals decorating the convent of San Pedro y San Pablo, the National Preparatory School, and the Ministry of Education through the next few years. The artists employed included Leal, Charlot, Siqueiros, de la Cueva, Alva de la Canal,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Revueltas, Dr. Atl, Montenegro, Orozco, and Mérida. In the beginning these men were organized into a "Syndicate of Technical Workers, Artists, and Sculptors", whose general program of a socialized artistic expression, based on native tradition and directed toward the aesthetic stimulation of the masses, was best expressed in a manifesto issued by Siqueiros in 1922.

The progress from revolutionary ideals to creative actuality recorded in the above mentioned murals suggests something of the vitality of the period. Experiments in the various mural techniques of encaustic, tempera, true fresco, and oil combinations resulted in the practical establishment of true fresco as the standard medium. The attempt to create a national "people's art" produced a renewed study of Mexico's artistic heritage, which included not only the transplanted styles of the official church and academy but esp. the Indian traditions of ancient Mexico and the native popular arts produced and used by the great masses of people. These indigenous traditions were studied and exploited by the artists, who at the same time were fully aware of the stylistic innovations in color, design, and aesthetic purpose developed by European modernists. The search for an adequate content capable of expressing the ideals of the new revolutionary Mexico varied from traditional mythological, historical, and religious subjects to a new type of socio-political symbolism growing out of the revolution in a form most closely related to the caricature and propaganda of the popular press.

The dynamic integration of these problems of technique, native aesthetic tradition, international modernism, and a significant content is essentially what constitutes the Mexican style and is to be found in work of Orozco, Rivera, Charlot, Leal, Siqueiros, and Montenegro before 1924. However, one factor which the movement failed to accomplish was an effective organization through which this interpretation could be maintained. The ideal of artistic cooperation envisaged by the Syndicate under the personal patronage of Vasconcelos was soon dissipated by political intrigue and personal ambition. After the removal of Vasconcelos as Minister of Education (1924), the history of modern Mexican art is largely the records of individual artists.

The most productive of these, esp. in mural decoration, have been Orozco and Rivera, whose works and activities, along with those of Siqueiros, are largely responsible for the fame and recognition of Mexican art outside Mexico's borders. The ideological content of their painting likewise has shifted from purely Mexican problems to those of larger and more universal import. Rivera's fresco for Rockefeller Center (destroyed and repainted in Mexico's Palace of Fine Arts) and the vast murals which Orozco has painted in Guadalajara and Jiquilpan are particularly important from this point of view.

The work of the other Mexican painters has followed three main directions. One group has sought to continue with scattered government commissions the ideological patterns of Vasconcelos and the original Syndicate (e.g., Leal, Montenegro). A second group composed of younger artists, most of whom had worked as assistants to Rivera, followed the general social and stylistic program developed under his tutelage (e.g. Pacheco, O'Higgins). A third group, also of younger men, repudiated, at least temporarily, the Vasconcelos program and concentrated on easel painting (e.g. Lozano, Mérida, Tamayo, Castellanos, Lazo, Diaz de Léon, Mendez). They were no less idealistic and patriotic about the achievement of a modern and distinctly Mexican style, put they also felt the need of the technical discipline and personal expression which only the easel painting affords. For a direct contact with a larger public, many of these artists have turned to the graphic arts in works dealing with social problems (Mendez). For a period before the outbreak of World War II, the government had awarded a number of mural contracts to these younger men (Tamayo, Castellanos) who produced works that suggest the possibility of a new and greater development. *dores,* whether military, civil or religious, had an improvised and rather stylless character more dependent on immediate necessity, available materials and the building skills of native labor than on any memory of Spanish styles or on the impressive but unadaptable monuments of vanquished Indian civilizations. But within a generation, by 1550, when the conquerors had become colonists, the situation had changed: the City of Mexico had been rebuilt with semi-military plateresque palaces, and new towns were rising throughout the land with orderly streets and plazas dominated by huge stone fortress-monasteries, the most important monuments of the 16th cent. Their churches were usually aisleless with a polygonal or square apse to the east and a choir raised on a gallery over the western door; they were covered by barrel or traceried Gothic vaults, and buttressed by massive inert walls and salient pier buttresses; they were unroofed and elaborately battlemented, and occasionally equipped with a *chemin-de-ronde.* Towers were plain; often they were lacking entirely; in some regions bells were hung in the arches of a pierced gable, or *espadaña.*

South of the church there was usually a two-storied cloister surrounded by the various rooms of the monastic establishment. In front was a vast forecourt, or *atrio,* enclosed by a crenellated wall. Here congregated crowds of converted Indians for catechism, baptism and outdoor mass, celebrated by a priest in a special chapel connected to the monastery building but broadly open to the *atrio.* (In Yucatán an apse-like open chapel often took the place of the church.) In the corners of the *atrio* stood four small shrine buildings, or *posas,* with altars used during outdoor processions. This arrangement for congregational worship in a large walled court, with a multitude watching, in passive participation, a ritual performed in a special covered and often raised chapel may possibly be a borrowing—and the only one—from pre-conquest pagan religious architecture.

Many styles flourished simultaneously in the 16th cent., even side by side in the same building. Elements of Gothic design occur not only in the vaults, but also in portals, rose windows, gargoyles, the pointed arches of windows or cloisters, and in the decorative details of bases or moldings. Plateresque motives often dominate whole façade compositions and the architectural framework of the many-storied *retablos.* The façades of most of what little civil architecture survives are plateresque also. Another school of purer and more academic Renaissance architecture is to be found in a small group of Italianate basilican churches and occasional purist doorways and arcades. Mudéjar and direct Moslem influence is surprisingly strong,—in mosque-like open chapels, in *alfarje* ceilings, in *alfiz* doorways and windows. Even more exotic is the occasional *manoelino* or the vague reflections of styles already extinct in Europe, such as the romanesque. Carving in any of these different styles is subject to reinterpretation at the hands of Indian craftsmen, resulting in a unique stylistic blend, the *tequitqui.*

The great cathedrals which began to rise at the end of the century represent a less vigorously and more sophisticated or Spanish development than the monastic churches, for they were designed by imported professional architects and not by amateur monk-builders like most of the monasteries. They were begun on late Gothic plans in imitation of Seville or Salamanca, but developed with increasingly decorous Renaissance detail which submits, at the end of the century, to the severe discipline of Herrera. Decorations and additions of subsequent periods have now changed these XVI century cathedrals into historical museums of the development of Mexican architecture rather than exemplars of any one style.

*17th Century.* The characteristic church is no longer that of the monastery, but the parish church of the secular clergy. In one of the world's most assiduous fervors of religious building, more and more new churches were raised throughout the country (perhaps some 8,000 in this century alone). In the towns of the more prosperous agricultural regions and near the incredible mines, these were built with an opulence eclipsing contemporary work in Spain. The simple basic scheme is rarely varied: everywhere appears the same high aisleless nave (sometimes with shallow side-chapels), shallow transept and square apse; a high dome covers the crossing and its openings supply the main light for the interior. The façade is usually adorned with a frontispiece of sculptured ornament contained in an enframement of the orders; the larger compositions of more than one story recall the handsome gilded *retablos* within. (A few are even concave like apse *retablos.*) The frontispiece is flanked by one or two towers, plain below but elaborately ornamented in the open belfry section above. The whole construction is no more than a neutral

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

background for the decoration of portal, tower and dome.

The general style is loosely known as Mexican baroque, though the only baroque elements are decorative, and are freely mixed with mannerist and occasional mudéjar forms. There is almost no baroque planning or spatial composition. The baroque character lies rather in the decoration,—an agitated profusion of twisted columns, broken pediments, cartouches, swags and brocade-like relief patterns arranged with the carefree independence of a country with no classical traditions but with an innate sense of ornamental logic and ordered exuberance. Though its sources are Spanish, the finished architecture is not.

Monasteries were still being built, and now also convents, usually in the cities where, though they had to be more restricted in plan, they became even more sumptuous in decoration than their XVI century predecessors. Their church-type is like the parish church, but generally without transept and with two decorated portals on the flank facing the street rather than one at the end of the building.

The rich colonial families built themselves stately rectangular palaces with rectangular patios, again on a simple standard plan in no way baroque, but with a wealth of baroque ornamentation on the mammoth entrance, or *saguán,* and in the arcaded patio and its fountain. The parapets which crown the walls are often animated in silhouette and pulled up at the corner to form the cresting of an *hornacina* or angle niche for the figure of the patron of the house. Town halls and the administrative buildings of the government followed the same palace type, sometimes with the addition of a tower and arcades across the main front.

Materials were more varied than in the preceding century. Glazed tile made in Puebla was freely used to cover whole walls, exterior and interior, and to make brilliant the many domes which dominated every town. In Mexico City the favorite building material was *tezontle,* a soft wine-purple lava, in Oaxaca and Guanajuato a green limestone, and in Morelia a peach-colored trachyte. Elaborate low stucco reliefs covered the walls of many palaces in Mexico City in all-over diaper patterns, half mudéjar, half baroque, and in Puebla stucco curled and sprang free of the walls in a filigree of strap-work derived from mannerist engravings of ornament but so developed and so vivified as to constitute a startlingly original baroque style. Church interiors in this and the succeeding century were emblazoned with more gold leaf than the world has ever seen in architecture before or since.

*18th Century.* The building types of church and palace remain much the same, but the decorative elements become more varied and more important, advancing over the building until they efface any other major architectural interest. Ornamental interest does not smother or conflict with tectonic architectural interest: it replaces it.

The several extravagant styles of the first three-quarters of the century are usually classified together under the term *ultra-baroque.* The most important of these is the Churrigueresque, radiating from Mexico City but so widespread by 1760 as to constitute a national rather than a local style. It reaches its fullest expression in façade frontispieces and *retablos* (which seem to have influenced the façades), but has such a definite character and vocabulary that it can easily be identified as well in the details of doorways, windows or niches. Its main element is the "Churrigueresque order", made up of a pedestal with *faldoncito* (lambrequin ornament), a shaft in the form of an *estípite* (inverted obelisk) surmounted by a medallion block and a Corinthianesque foliate capital, and an entablature repeatedly broken in plan and again in elevation by openwork foliate brackets on axis with the shafts and keystones, etc. Moldings have bold deep unclassical profiles, and rarely run uninterrupted, but change their direction constantly and consistently in a typical sequence of straight and curved segments. This style is as extravagant as the Churrigueresque of Spain—possibly more so—but it is more disciplined: it uses a more standardized repertory of forms and lines, and submits to much stricter compositional laws. But this careful marshalling of many parts is the means to quite a different end, for the sensuous effect of a complete Mexican Churrigueresque interior is undeniably and purposefully overwhelming.

The tile work of Puebla extends its repertory until entire large baroque compositions in glittering and brilliant color are pieced together not only on flat surfaces and domes but also on cornices and columns, on capitals and *estípites* and almost every external architectural feature no matter how complicated its form. Palaces in Puebla are commonly of bright red tile dotted with indigo lozenges. Tile coverings for domes were made in Puebla in all colors and sizes and sent on mule-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

back to every part of the country, from Arizona to Campeche.

The 17th cent. stucco work of Puebla and its satellites in the States of Mexico, Tlaxcala and Oaxaca develops an even less architectural character in the 18th cent. as it comes to play a more important architectural role. Cornices are made to ripple and crinkle with rococo bravura giving rise to many legends of stucco mixed with sugar or white-of-egg. In the most extreme examples, the filigree of free-standing strap-work exhibits a really bewildering virtuoso luxuriance.

There are other important local styles identifiable in Mexico City, Querétaro, Morelia San Luis Potosí, Oaxaca, etc., and ingenuous versions of all of them in the folk-architecture of the Indian villages.

Towards the end of the century, academic influence is brought by imported architects and imported engravings imitated by Mexicans. French models supplant Spanish and correctness supplants invention. National character and originality dies with the chill *rigor mortis* of provincial international classicism.

*19th and 20th Centuries.* The 19th cent. was so troubled politically that there was little building before the parvenu period of Porfirio Diaz at its close: what little there was followed fashionable European models from Empire neo-classicism on down to Parisian Art Nouveau at the beginning of the 20th cent.

Since 1930 there has been more building in the modern style in Mexico City than in any other city in the world. At first it was just another importation, façades from Europe and structural methods and conveniences from the United States. Construction is unusually timid in span of beams and in structural systems chosen: reinforced concrete is ubiquitous, even in very small buildings. The surprisingly varied native materials have been little exploited, nor has serious study been made of the peculiar regional climatic conditions except in hospitals and schools. Though widely accepted in Mexico, modern architecture has not yet developed a vigorous national character comparable to the colonial styles. Some of the most recent work seems to indicate, however, a more autochthonous new movement, a worthy companion to the better known achievements in modern Mexican painting. —J.McA.

**mezzanine.** A low intermediate story between two higher ones.

**mezzo-recitativo.** See opera.

**mezzo-relievo.** See relief; relief sculpture.

**mezzotint** (an intaglio process). The process of making mezzotints is similar to making drypoints, only the process is reversed. A burr is raised over the surface of the entire plate. The plate, if printed before any work was done, would produce a solid black. All parts of the design, which should print lighter than black, must be scraped. For a pure white the original smooth surface of the copper is retained.

The process of roughening the surface of the plate is such a laborious one that only few artists have the courage to carry it through. It is accomplished by using a tool called a **rocker.** This is a steel chisel having a curved edge serrated with very fine teeth, the handle springing from the center of the curve. The surface has to be rocked with this tool in many directions, each time taking a definite angle, until the surface of the copper is cut all over into a minutely dotted surface, which holds the ink as does the burr of the drypoint. To overcome this laborious process, the Cleveland Print Makers roughen the surface by sand blasting; Alex Stavenitz, the American artist, uses the aquatint method, calling it "aquatint mezzotint." The carborundum prints made on the Federal Art Project in Philadelphia are obtained by grinding the plate with a lithograph levigator, using carborundum and water.

Mezzotints are outstanding for their richness of blacks. The process is one that will reward the artist who has the will to do the work and explore the subtle range of tones. See PRINTS AND PRINT PROCESSES. —K.K.

**mihrab** (Arab.). The prayer niche in a Mohammedan mosque which indicates the direction of Mecca, the holy city of all Mohammedans. Frequently used as a motif in the design of the antique Ghiordes prayer rug. See ISLAMIC ART; PERSIAN ART.

**military sketching.** The conveying of military information by means of hastily drawn maps

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

or landscapes. There are three chief forms: (1) **military sketches** proper are maps made in the field by *plane-table* surveying methods, in which directions are ascertained by sighting along an *alidade* or ruler or by means of a compass, distances usually by pacing, by intersecting sight rays or by estimation, and relative elevations ordinarily by measuring vertical angles with the aid of a *clinometer* or by sighting along the edge of a board to which a plumb line is attached. (2) **Aerial photo sketches** are maps made from combinations of aerial photographs, often with the assistance of some form of *stereoscope*. (3) **Panoramic sketches** are simple, literal landscapes with notes pointing out the features that are of military importance. These latter sketches are commonly made by holding the edge of the drawing against the view, keeping it at a constant distance from the eye by aid of a knotted string held in the teeth, and marking on the edge of the paper where it cuts across important details of the scene as observed with one eye closed. These marks are then extended to appropriate places in the drawing by means of faint lines parallel to the edges of the paper. By this means soldiers with little artistic experience are often able to make drawings of sufficient accuracy to serve well their military purposes. See U. S. War Department. *Field Manual 21-35. Field Service Pocketbook: Sketching.* —T.I.C.

**mille fleurs.** See TAPESTRY.

**Mimbres art.** A unique pottery is the chief expression of a people who lived in the Mimbres River Valley in southwestern New Mexico c. 1000-1200 A.D. It consists of somewhat irregular food bowls of black on white ware, decorated on the inside with figures of birds, insects, fish, animals and human beings, drawn with a lively naturalism but conventionalized enough for decorative purposes. In marked contrast to the highly abstract quality of most ceramic decoration in the Southwest, all the creatures seem strangely alive. An irregular hole broken in the bottom of many of the bowls indicates burial use; probably the spirit of the bowl was supposed to be thereby released to be free with the spirit of the deceased. So entirely unique and so localized in time and place is this ceramic ware that some scholars have suggested that it is the work of some gifted individual or school of potters. See H. S. and C. B. Cosgrove, *The Swarts Ruin; a Typical Mimbres Site in Southwest New Mexico,* Peabody Museum Papers, 1932. —H.G.

**mimodrama.** A pantomime, often accompanied by music.

**Minai ceramics.** See ISLAMIC ART.

**minbar** (Ar.). Pulpit in a mosque. See ISLAMIC ART.

**Minerva.** See Athena.

**Ming art.** See CHINESE ARTS.

**ming ch'i** (Ch.). Modeled clay figurines for burial in tombs.

**Ming dynasty porcelain.** See CERAMICS II.

**miniature painting.** See EARLY CHRISTIAN ART.

**minima.** See NOTATION.

**minium.** Strictly, this is the red tetroxide of lead made by heating litharge or white lead for fairly long periods and at fairly high temperatures. It is bright scarlet in color, has good hiding power, and a smooth texture in oil. It has been used generally in European and Asiatic paintings since ancient times, although the word, minium, was also applied to cinnabar or natural sulphide of mercury. —G.L.S.

**minnesinger** (Ger.). German troubadours of the 12th and 13th cent. of noble lineage who composed both words and music of their songs. See MEDIEVAL MUSIC.

**Minoan architecture.** See Aegean architecture.

**Minoan art.** See Aegean-Minoan art.

**minor interval.** See interval.

**minor mode.** See scales and modes.

**minor scale.** See NOTATION.

**Minpei yaki** (Jap.). Pottery made in Awaji province.

**minstrel's harp.** See MUSICAL INSTRUMENTS.

**minstrel show (Negro minstrels).** A species of musical and variety entertainment which had its origin among the Southern Negroes in the U.S.A. and which was popularized in theatrical presentation by E. P. Christy, the originator in 1842 of a troupe of imitation Negro singers, musicians, and comedians. The company usually includes a men's chorus in black face, an interlocutor who announces

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

specialty numbers and who precipitates much of the comedy by interrogating two or more 'end men,' fantastically dressed specialty artists or comedians who sit in special chairs on the flanks of the chorus. Although minstrel shows originally employed dialect songs of Negro life, including some which Stephen Collins Foster wrote for Christy, modern performances emphasize popular music. Yet the bones, banjo, and tambourine, the latter employed by the chorus in intricate routines, still are used as accompanying instruments. Variety acts, acrobatic stunts, dramatic sketches, and other performances now are usually included with the minstrel show. Christy took his troupe to England, where this form of entertainment achieved a lasting popularity. —H.R.W.

**minuet.** The minuet, which was to become the most famous of all court dances, originated among French peasants as one of many branles of Poitou. Since its music became part of the later instrumental suites, it is called a pre-classic dance form. In its original state, this branle was a gay and lively dance in ¾ meter. Its healthy vigor is reflected in the writing of a 16th cent. authority who mentioned the girls of Poitou stamping with their wooden sabots to mark the phrases. After the 18th cent. courtiers had made the dance over to reflect their own sophisticated artificiality in small, precise movements, they gave the branle a new name based on the word *menu* (small, neat). The court dance took on a great complexity of mannerisms and etiquette associated with its performance until it became and remains a symbol of foppish elegance. —J.G.

**minuscule.** Small letter. See writing.

**mirror canon.** See canon.

**mirrored color.** See COLOR.

**Mirror of the World.** See ORIENTAL MUSIC.

**misericord.** A projection from the under surface of quirestall seats in Gothic churches placed so that when the seat is turned up it can be used as a support for a standing priest during a long church service. Therefore the name "misericord"-instrument of pity. Often (England!) profusely decorated with humorous scenes or representations from the Bestiary (q.v.). —R.B.

**modeled.** See SCULPTURE.

**modeling.** (1) The act of forming a two or three dimensional figure in a plastic, malleable material such as clay or wax, the resulting figure being either retained as the end-product, or used as a model or form for the making of a reproduction in plaster, terracotta, bronze, marble, stone, or wood; (2) that quality of a painting, drawing, photograph, or other two-dimensional representation in which an effect or illusion of the third dimension is achieved, through the use of such means as lighting, contrast, color, and perspective, and control of dark-light values. Whitford and Winslow in *Dictionary of Education.*

**model drawing theory.** See PERSPECTIVE.

**mode of vibration.** See ACOUSTICS.

**modern architecture.** See international architecture.

**modern copies of paintings.** See FORGERIES IN PAINTING.

**Modern dance** is a concept—a point of view—and not a prescribed system. It is dance as it is conceived today in terms of its science, philosophy, and art. It inherits much from the past and is influenced by the scientific spirit of the present. Its study is profiting from increased knowledge of movement and rhythm. Physiological and psychological research have revealed the nature of the kinesthetic sense and its importance to motor and rhythmic perception. This research has also revealed the relation between feeling and its movement expression—revelations which are influencing the technical study of dance, as well as its theory and philosophy. As a result there has been a general agreement as to the basic meaning of dance. The emphasis today is to know and experience dance as a creative art experience, expressing and communicating the dancer's emotional reactions to his impressions, as he evaluates them. The technical necessity is to train the body to become a strong, flexible, sensitive and well-coordinated instrument capable of responding to the exigencies of the expressive mind. The quality and manner of movement are determined by the artistic integrity of the dancer rather than be a forced conformity to an externally imposed standard. Moreover, compositional form is no longer dependent upon musical forms. It emphasizes the necessity of the outward observable form (the dance) being an organized structure that meets the requirements of subject matter, instead of the requirements of a pre-determined structure. Dance has proved its ability to compose independently in its own medium (movement), creating dance forms as objects of art in the same sense as a painting or musical composition is an art object. The expressive forces of dance are known to be embedded in muscle tension, and in the tensions arising from stresses inherent in structure itself. Today dance is free to choose for its accompaniment from a variety of possibilities: speech, song, sound effects, as well as music.

Modern dance is the contemporary phase of dance in its evolution toward its destined goal of greater universality.

The term "modern dance" should not be confused with the personalized dance manner of contemporary artist dancers. —M.N.H'D.

**MODERN STAGESETTING.** The development of modern stagesetting cannot be explained by one common denominator. Any attempt in this direction would unevitably leave out some of its sources, trends, and facts. Nor can we explain the development of its artistic values by the development of its machinery or of the technique of lighting functionally.

The 19th cent., unsensual as it was, represented the poorest level of stagesetting for many centuries. The first protest against its conventional and trivial rendering was launched by the Duke George II of Saxe-Meiningen about 1874, whose group under his leadership played on many European stages. Besides his ideas as to directing, his ambition was to make the setting as "true" as possible; however, for him truth was identical with reliability of historical details. Thus he crowded the stage with an unbelievable number of individual items. This method was interesting for the historian but it was irrelevant from an artistic point of view, since the result was a collection of three-dimensional props before sidewings and backdrops painted in the old manner. Anyhow, the naturalism of the beginning 20th cent. can be followed back to the stimulus he gave to the European stage.

The first step forward in the 20th cent. was done by Constantin Stanislavski (1863-1938) with his Moscow Art Theatre. His work is characterized by the most truthful realism of the minutest details which now included be-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

sides the three-dimensional props solid side walls instead of the earlier flats. While the **Meiningers** believed that the mere addition of realistic details was already enough in itself, Stanislavski tried to organize these details in a kind of selective realism and to create in this way the mood of the scene. However, the naturalistic style of Stanislavski meant a perfection and an end and not a new beginning.

Max Reinhardt 1873-1943; started in Berlin 1905) added to the three-dimensional naturalism the lavish use of the meanwhile invented new machineries, such as the revolving stage, the cyclorama, wagon stages, etc. The artist to whom he gave the tasks of stage design like Alfred Roller, Emil Orlik, and especially the most versatile of them, Ernst Stern, combined the most contradictory trends, adding to his naturalism some elements of stylization. Because of this mixture we are not able yet to find out whether Max Reinhardt, in any case one of the most sensational theatrical genius, represents, after all, the climax of a period gone or can be considered as the pioneer for a new one. Anyhow, from a sociological viewpoint, he was at least the first in Western Europe who saw the difference of the artistic demands of the intimate theatre and the theatre of the masses which found its greatest development later in Russia. Reinhardt created *Kammerspiele* as well as an experimental theatre for the masses with his central-domed *Grosses Schauspielhaus* in Berlin, 1919, which was shaped by the tendency for the inclusion and greatest participation of the audience. In this way he continued Richard Wagner's (1813-1883) fight against class differentiation in his Festival Theatre at Bayreuth. Reinhardt's naturalism although based on the rendering of naturalistic details used, however, also elements of a movement which simultaneously fought vehemently against all kinds of realism. It was the trend for which two men were pioneers: Adolphe Appia and Edward Gordon Craig.

Adolphe Appia (1862-1928) in order to develop further the ideas of his master Richard Wagner considered the theatrical performance a *Gesamtkunstwerk* (q.v.), a combination of visual, acoustic, musical, and literary impressions, connected and united by rhythm. (*La Mise-en-Scène du Drama Wagnerien,* Paris, 1895). He concentrated mainly on the development of the three-dimensional built-up and the psychology of color and light, shaded according to rhythmical laws. The actor's proportion had to become the unit of measurement and the law of space had to correspond to the time law of music. These rhythmical laws which governed music, the movement of the actor, and the visual and spatial forms by a kind of orchestration of light equally, became later even still more evident in the theories of Jacques Dalcroze (b.1865) with whom he worked at Hellerau-Dresden, Germany.

Edward Gordon Craig (born 1872), not quite so revolutionary in his "purification of the stage" as he himself believed, emphasized the architectural organization of the stage by simplifying all details and reducing them into pure cubic volumes. Undisturbed by any technical inhibitions in his projects he changed the proportions of reality arbitrarily, used steps and platforms thus stimulating our feeling for space—helped by the influence of the dance, by distributing the actions on different levels. Later on he renounced even specific architectural forms, and composed the whole stage by portable folding screens in manifold combinations. He considered the "divine" movement as the basis of theatrical art and reduced even the role of the actor, demanding absolute craft, his ideal being the "inanimate" being, the super-marionette. Since he could not achieve this kind of theatre, he at least made the stage more rhythmical by introducing rhythm within a scenic unit into the stage decoration. Thus he contradicted naturalism even stronger than Appia, exercising a tremendous influence upon the theatrical world by his organ *The Mask* since 1908.

Already before World War I, while Stanislavski's and Reinhardt's naturalism still flourished, while Appia's and Gordon Craig's stylizing influence still grew, new ideas began to arise again in Russia. Vsevolod Emilievich Meyerhold (born 1873), formulating his "biomechanical" principles, tried to shape a stage entirely in correspondence with the needs of the actor's body and movements, emphasizing gymnastic displays. Thus he was lead to a stereometric subdivision of the stage by the abundant use of steps and different levels, too. Of course, the whole tendency of the Russian theatre for the "mobilization of the will of the masses" contrary to the entertainment theatres, influenced also the selection of the visual means. It was Leopold Jessner in Germany, 1919, who took over these stimuli, creating the world famous *Jessner Treppen* which were of strongest influence on the stage of the U.S.A.

Alexander Tairov (born 1885) in his "liberated theatre" went one step farther. He put scaffolds and technical constructions on the stage of the Kamerny Theatre in Moscow

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

(already in 1914) without any ambition to have them interpreted as real localization of the respective scenes. His "Neo-Realism" insisted on the visibility of all constructive elements since his functional mind wanted to abolish all stage illusion and to show even the machinery as it really was. Since the whole world of theatre in itself is unreal and becomes real only through a tacitly accepted convention, this limited reality denies the frame of its art and must logically make the actor also a mere "instrument." In spite of this inner contradiction his main designer Alexandra Exter succeeded in creating bizarre constructivistic patterns always leaving free planes for histrionic action. Sometimes Tairov played even before the curtain, negating any kind of setting, sometimes he used the whole depth of the decorated stage.

It should not be forgotten that the so-called "mechanistic reproduction" relied on stimuli which went out from Tairov. So the *Locomotive Ballets,* the *Triadic Ballet* by Carl Schlemmer, the *Machine Ballet* by L. Lissitzky (1924, Vienna), by Slivinsky in Warsaw with their corresponding settings can be retraced to his ideas as well as the overemphasis on machine elements, which was so characteristic for the Jewish Moscow Academical Theatre.

In Western Europe, meanwhile, cubism and futurism had stimulated the stage, too. Reality was dissolved into rhythmically arranged stereometrical patterns (the Italian Francis Picabia, Antonio Bagaglia, Enrico Prampolini), settings which sometimes looked like retranslated cubistic paintings. The last step in this direction was done by the artists of the Bauhaus, Moholy-Nagy and Oscar Schlemmer who extended the abstraction not only on the stagesetting but also on costumes and even on the mechanically organized movements of the actors, partially, as mentioned above, stimulated by Tairov.

In connection with his ideas of the political epic theatre Erwin Piscator (b. 1893) in Berlin influenced also the visual means of stagesetting. He used the theatrical machinery as a medium of his ideas almost to the same degree as the actor. The **revolving stage,** invented in 1896 by Karl Lautenschläger in Munich, had been already used by Max Reinhardt but only for realistic purposes. Now it became an expression in itself like the elevator stage, originated by Alfred Linnebach, or the treadmill. In combination with the abundant use of different levels these devices revolutionized the stage into a tribune of continuous three-dimensional action. These means were complemented by the lavish use of Mariano Fortuny's (1838-1874) diffused light which had been already introduced in 1909 in Berlin in combination with the **cyclorama.** Projection of still-pictures and of films helped the clarification of the political ideas which were to be propagandized as did the acoustic explanation of the narrator besides the actors. Dimensions, proportions, light and color were not any longer bound on any laws of reality. There were no visual means from Gordon Craig and Appia to Meyerhold and Tairov, to Schlemmer and Gropius (Bauhaus) which were not used in these highly dynamic settings.

The so-called **Architectural stage** as realized in the Théatre du Vieux Colombier, Paris, by Jacques Copeau (born 1878) and Louis Jouvet (b. 1887) around 1920, the "Shakespearian" stages by William Poel of the Elizabethan Stage Society of London, and some German reconstructions like Max Reinhardt's "Redoutensaal" in Vienna, 1923, were stimulated indirectly, too, by Gordon Craig. Adapting either the Palladian or the Shakespearian stage to modern needs, the scene represented a definitely given architectural environment with permanent setting. Hints of the locale of acting were given by some realistic smaller props. Other architectural stages with permanent setting: the Théâtre DuMarais, Brussels, 1923, and two theatres at exhibitions, Van de Velde's at the Cologne Exhibition, 1914 and Auguste Perret's at the Exhibition of Decorative Arts, Paris, 1926.

The first step towards the formal architectural stage had been done already by Alfred Roller, Vienna, 1905. But in his works (as well as in those by Oscar Strnad [1880-1935] and Carl Czeschkà for Reinhardt in 1908) the Austrian exuberant sense for decorative effects smoothed the rigid scheme—as was the case in the Künstlertheater of George Fuchs (b. 1868) in Munich. Hence today we, looking backwards, appreciate much more the decorative elements of these settings than the elementary architectural idea which was so strongly emphasized in the theoretical writings of these reformers.

The permanent architectural setting, realized in this country for the first time by the Arts and Crafts Theatre, Detroit, 1917, which used also the portable screens of Edward Gordon Craig, was always connected with very definite ideas about the relation between auditorium and stage. The theoretical writings by George Fuchs (*The Future of the Theatre,* Munich, 1905), the Russian projects like the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Mass theatres at Kharkov and at Rostov-on-Don, the Grosse Schauspielhaus, Berlin, by Hans Poelzig, 1919, and the ingenious project of Walter Gropius and Erwin Piscator (where not the stage but the auditorium was rotating), and in this country, the projects by Norman Bel Geddes (b. 1893) and William Lescaze (b. 1896), all of them stressed the desire for a closer contact between audience and stage and a stronger participation of the audience in the performance which helped create these ideas. Generally the trend from stylized realism toward the even stronger suppresion of reality increased immensely after World War I. The locale of action was merely hinted, architectural forms, color and light, even directions of movements served mainly the purpose of expressing the mood of a given scene. Thus stylization brought the scheme into harmony with the essentiai spirit of the play. One single prop, one street lantern, one tree, one staircase, one Gothic arch became the symbol or "expression" for an environment whose further details were not shown.

In contrast with all these more or less architectural, more or less symbolic, more or less abstract tendencies, an outspoken contradictory movement developed simultaneously; the exclusive emphasis on painting and the use of stage perspective. However, now the idea is not one of illusionistic deception like in the 19th cent. On the contrary, it is a play based on disillusion, showing clearly that the make-believe of perspective and painting is just a make-believe and has to be looked at quasi, "in quotation marks". Currents of contemporary easel painting were transferred to the stage, from impressionism to cubism and futurism; it meant the negation of any spatial setting and the triumph of the consciously two-dimensional decoration. It meant a deceit which negated itself, a pattern for its own sake in which the actor, mainly the bearer of a costume, was just another element of the decoration. The chair, obviously painted on the wall, was just the ultimate step in this direction. This line to exaggerated artifciality began with Leon Bakst (1866-1924) and his formalistic Byzantinism and was taken over by the painters Fernand Léger (b. 1881), Henri Matisse (b. 1869), George Braque (b. 1881), Pablo Picasso (b. 1881) and André Dérain (b. 1880) between 1920 and 1930 in their settings for various ballets. Even those Austrian and German painters who generally worked in another direction, like Alfred Roller, Vienna; Oscar Strnad, Vienna; Ernst Stern, Berlin; Panos Aravantinos, Berlin; and George Grosz played sometimes with these ideas.

The American theatre was fortunate in so far as all these contradictory individual trends were not fought out in this country. After the period of David Belasco's (1859-1931) substantial naturalism, American stage designers, far less dogmatic than the revolutionary pioneers of Europe and Russia, took the new ideas from wherever they found them, fresh and independent, being less bound by theories. The majority of American theatres continued in the old manner till the period between 1925 and 1930—unfortunately some of the greatest still today. Only then the new stimuli began to express themselves in the work of American stage designers. However, this delay was highly rewarded by the consequent freedom of choice. Thus it is impossible to identify leading masters with one of the above mentioned specific movements. Works by Donald Mitchell Oenslager (b. 1902), Robert Edmund Jones (b. 1887), Norman Bel Geddes (b. 1893), Cleon Throckmorton (b. 1897), Mordecai Gorelik (b. 1899), Boris Aronson (b. 1900), Joe Milziener (b. 1901), Harry Horner (b. 1911), Claude Bragdon (b. 1866) combine the colorful use of light of Adolphe Appia, the architectural attitude of Edward Gordon Craig, the expressiveness of the Germans of the 1920's with the constructivism and dynamic of the Russians. They use the artistic possibilities of the most complicated machineries but they are not ashamed to be sometimes entirely naturalistic in the way of Stanislavski and the early Reinhardt, if the conception of the specific play is asking for it. In other cases they are equally not ashamed of relying on the charm of playfullly painted settings in the line of the Russian Ballet. Small community theatres, college theatres and experimental stages are the pioneers, the commercial Broadway theatres follow quickly up. It is due to this spontaneity and entirely undogmatic attitude that the American stage today represents the highest development of stage-setting in the world, unhampered by the obliging traditions of past revolutions. **modes, ecclesiastical.** The ecclesiastical modes (not to be confused with the ancient Greek modes) which form the basis of medieval music are eight in number—four authentic modes, and their derivative plagal modes. An apocryphal tradition ascribes them to St. Ambrose (c. 340-97) and Pope Gregory I (c. 540-604) respectively.

| | *Authentic* | *Plagal* | *Range* | *Dominant* | *Final* |
|---|---|---|---|---|---|
| Dorian | I | | D-d | a | D |
| Hypodorian | | II | A-a | f | D |
| Phrygian | III | | E-e | c | E |
| Hypophrygian | | IV | B-b | a | E |
| Lydian | V | | F-f | c | F |
| Hypolydian | | VI | C-c | a | F |
| Mixolydian | VII | | G-g | d | G |
| Hypomixolydian | | VIII | D-d | c | G |

The final for each pair of modes i.e. the authentic (composed of a pentachord and tetrachord) and its derived plagal (composed of a tetrachord and pentachord) a 4th below is the same, the difference between the two being one of range. In the authentic modes the dominant is a 5th above the final with the exception of mode III which during the 10th or 11th cent. was transferred to c. Use of the old dominant b, however, is often found. In the plagal modes the dominant is normally a 3rd above the final with the exception of mode IV a, and mode VIII c.

It is to be observed that there are no modes with a and c as final. The former occurs in isolated cases and is known as *tonus peregrinus.* The latter known as *tonus lascivus,* although condemned by the Church, was favored by secular musicians.

The mode of a plainsong melody is indicated by its appropriate Roman numeral in chant books. It is a simple matter to ascertain the mode of a melody. The last note is the final. If the compass of the melody lies within the final and its octave, it is authentic, if it lies within the 5th above and the 4th below, it is plagal. Occasionally a melody will extend over the entire range, in which case it is considered mixed. A b flat in the signature indicates a transposed mode a 4th above. In some instances e.g. *Agnus Dei XVIII* (*Liber Usualis,* p. 63) the mode is undetermined, indicating that the melody is a very ancient one dating from a period when the theory of modes was not yet developed.

The names Dorian, Phrygian, etc., were first applied to the ecclesiastical modes by Boethius (c. 480-524) who for many centuries was considered the greatest authority on ancient Greek music, Boethius translated the Greek term *tonos* by the Latin word *modus* and as a consequence arrived at a system of nomenclature which was the reverse of that of the Greek modes. —V.A.

**modes, musical.** See scales and modes.

**modes** (of appearance of color). See COLOR.

**modifications by the artist.** See FORGERIES IN PAINTING.

**modified fragments.** See FORGERIES IN PAINTING.

**modillion.** An ornamental block or bracket under the corona of the cornice in the Corinthian and other orders.

**Modra ware.** See CZECHOSLOVAKIA, ART OF.

**modulation.** (1) The rise and fall of the voice in speaking or reciting. (2) *Mus.*

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Any change of key or mode. See idiom B(3); key.

**Moghul art.** See ISLAMIC ART.

**Mogollon culture.** A culture of southwestern New Mexico, as yet little understood, contemporary with Developmental Pueblo and Hohokam, partaking of characteristics of both, yet with some peculiar to itself. Pit dwellings were used; a red and brown pottery was finished by the paddle and anvil method and polished. Shell gorgets suggest a connection with the East. Further evidence may prove that Mogollon was a local variation of either Anasazi or Hohokam. See Neil M. Judd, *Progress in the Southwest,* Essays in Historical Anthropology of North America, Smithsonian Miscellaneous Collections, 1940. —H.G.

**moire.** Finish on silk, cotton, or acetate fabrics of plain weave, often corded. Engraved rollers, heat and pressure flatten the surface at intervals, leaving the natural roundness in other places. —G.W.R.

**Moki art.** See Hopi art.

**mokuga** (Jap.). Literally, "wood picture"; a picture in marquetry, or wood inlay.

**mokume** (Jap.). A lacquer technique imitating the grain of wood.

**mold.** Plaster of Paris form in or on which ceramics are made. See CERAMICS I.

**mold-blowing.** See GLASS AND GLASSMAKING.

**moldings.** Slender surfaces often compounded which depend for their decorative effect upon the gradations and contrasts of light and shade.

**Momoyama art.** See JAPANESE ART.

**mon** (Jap.). A family crest used on family possessions, and sometimes conceived as pure design. See SYMBOLISM IN FAR EASTERN ART.

**monastic architecture.** The building groups provided for communities of monks or nuns who take vows of poverty, chastity, and obedience, living under the rule of abbot or prior (abbess or prioress) devoting themselves to prayer and various good works. Early monks in Eastern Christendom lived separately in scattered cells, meeting ceremonially at the monastic church for their liturgy and in the refectory for their meals. Later the various accommodations for the Eastern monks were regularly built against the inside of a fortified girdle wall, leaving the church standing free in a central court with the refectory facing it. In Western Christendom the church is normally to the north of the **cloister,** an arcaded garden court which is the center of the life of the community. A normal arrangement of the various rooms in a medieval monastery is as follows: Along the *east walk* of the cloister: 1, sacristy (adjoining the church); 2, **chapter house,** where the community met daily as a corporation to hear a chapter of the monastic Rule and to transact business; often there was a chapel extending further east, with the infirmary establishment for the old and the sick monks beyond; 3, parlor or auditorium for speaking (since silence was enjoined elsewhere for a large part of the time) and as communication to the easterly parts of the monastery; 4, camera or workroom. The dormitory extended over 1, 2, 3, and 4, with exit directly into the south transept of the church, or by stairway to the cloister. *South walk*: 5, **calefactory,** a social room, exceptional in that it was warmed; 6, refectory; 7, pantry; 8, kitchen or kitchens, with shops, bakery, stables, quarters for lay brethren and servants not far distant. *West walk*: 9, cellars and stores; 10, adjoining the church, cloister entrance. *North walk* along the church nave; scribes and the library were often installed here. The guest house was often north of the church nave, with the porter's cella in it or nearby; the hospice for poor visitors was in the vicinity, often southwest of the church.

These conventual structures have a simple and rather barn-like character until the 12th cent.; later they are often five vaulted constructions worthy to be compared with the churches. A general movement to replace the medieval monastic buildings begins in the 15th cent. Many fine monasteries date from the 18th cent., esp. in France. At this time they are assimilated to palace architecture in the prevailing mode. Monastery building, interrupted by the French Revolution, began again in the 19th cent., but these newer groups are almost universally poor and dull in design. See Curman, S., *Bidrag till Kännedomen om Cistercienserordens byggnadskonst,* 1912; Thompson, A. H., *English Monasteries,* 1913; Gasquet, H. E. Cardinal, *English Monastic Life,* 1919 (5th ed.); Enlart,

*Manuel d'Archéologie française,* Part II, tome 1, 1929; Evans, J., *Monastic Life at Cluny,* 1931, and *Romanesque Architecture of the Order of Cluny,* 1938. —K.J.C.

**Moncloa pottery.** See SPAIN, ART OF.

**monk's mound.** See Cahakia mound.

**monochord.** An ancient instrument for measuring intervals. See MUSICAL INSTRUMENTS.

**monochromatic color scheme.** See COLOR.

**monochromatic plus white specification.** See COLOR.

**monochrome painting.** See CHINESE ARTS.

**monody.** *Mus.* Style of composition in which a melody (usually written for human voice) is presented simultaneously with an accompaniment of chords. The term is used particularly with reference to the early forms of solo cantatas and operatic arias of the 16th and 17th cents. In this sense, monody is a special case of homophony (q.v.). The term is sometimes used in the sense of monophony (q.v.). See MEDIEVAL MUSIC. —E.K.

**monolith.** A stone of one piece, used to differentiate a column shaft cut from one block of stone from one built up in several drums.

**monophony.** *Mus.* Process of composition by which a single melodic line is presented without accompaniment. Sometimes also called monody (q.v.). The term monophony is sometimes used as a synonym of homophony (q.v.). —E.K.

**monoprint.** See monotype.

**monotype.** A print technique usually classified among the graphic arts. The picture is painted in full color on a non-absorbent surface such as a sheet of plate glass or metal with any sufficiently slow-drying paint and transferred to paper by direct contact with it, using a rubbing pressure on the back of the paper with any smooth, hard, rounded implement. Various effects are produced by manipulating the paint before the impression is made. To make additional copies of the same subject the plate must be repainted, thus the variations in color and design cause each print to be a unique proof rather than an exact replica. See PRINTS AND PRINT PROCESSES. —R.M.

**monstrance.** A *ciborium* designed as an *ostensorium* so that it will serve not only to contain but also to exhibit the consecrated host. To comply with this purpose the host is placed in a transparent glass cylinder which is put on a high foot and made conspicuous by profuse ornamentation. The introduction of monstrances in + 1300 is connected with the pronouncement by the church of the doctrine of transubstantiation according to which the host while retaining its outward appearance is miraculously transformed into the very body of Christ. To celebrate this miracle the church instituted the festival of *Corpus Christ* (1264) in the course of which a monstrance is used to carry the host in solemn procession and to exhibit it to the community. —R.B.

**montage.** See RADIO DRAMA; collage.

**montan wax.** See wax.

**monumenta musicae Byzantinae.** See eastern chants.

**mood effects, of music.** See EXPERIMENTAL PSYCHOLOGY OF MUSIC.

**Moqui art.** See Hopi art.

**moralities.** A later form of the mysteries (medieval plays) and may be regarded as a rudimentary form of the oratorio.

**Moravia, art of.** See CZECHOSLAVAKIA, ART OF.

**mordant.** The word itself is of uncertain origin, but its common application in the art of painting is to a method of gilding. There the word, mordant, is used to indicate an adhesive film which remains tacky for a long enough period to allow metal leaf applied over it to become firmly adhered. It is distinguished from water gilding, used for large flat areas on the panels of alterpieces, and the application of shell gold or powdered gold mixed with a medium as a thin paint. —G.L.S.

**mordent.** *Mus.* According to Philipp Emanuel Bach an ornament with the function to connect a note with another a second below, to increase their sound and to add splendor. Technically, the mordent consists of a quick interchange between the main note with its neighboring second below. —F.D.

**moresca.** See morris dance.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**moribana style.** See FLOWER ARRANGEMENTS.

**moroccos.** *Book.* All genuine moroccos must be made from goatskins, which vary in quality according to the country from which they are imported. (Cape, French, Levant, Niger, Oasis, Persian, Swiss, Titling, Turkey.)

**morris dance.** This famous English national dance is of uncertain origin. Some authorities find proof of descent from the Moorish dance, the morisco, in the name "morris" and the fact that the dancers sometimes blacked their faces. In its earliest performances, the morris made use of pageantry portraying characters from the Robin Hood legends, and was danced exclusively by men. Some of the characteristic features of the dances were the wearing of bells, the use of swords, the waving of white kerchiefs, and the carrying of short sticks rapped together in complicated rhythmic patterns. The basic formation was two lines face to face. The most characteristic step is said to have been a cut—step and hop with a sharp forward kick of the free leg. Most morris dances were in 4/4 or 2/4 meter. —J.G.

**mosaic pictures.** A decoration or picture made by inlaying small pieces of variously colored glass, stone or other materials. In photography, a detail photograph formed by matching a number of photographs of contiguous parts taken from the air. See EARLY CHRISTIAN ART. —R.L.W.

**Moscow, school of.** See RELIGIOUS PAINTING IN RUSSIA.

**Moslem art.** See ISLAMIC ART.

**mosque.** See ISLAMIC ART.

**Mossi art.** See AFRICAN NEGRO ART.

**motet.** *Mus.* A composition in contrapuntal style, sung in Catholic and Lutheran services. See MEDIEVAL MUSIC.

**motif.** *Mus.* Structural unit, usually a short figure of characteristic melodic and rhythmic, sometimes also harmonic outline, susceptible of being varied extensively and of appearing in different contexts in order to ascertain structural relations between various parts of a musical form. —E.K.

**motif, of a design.** See design.

**MOTION PICTURE.** The motion picture is the one new art of modern times, and the most popular of the arts today. Both its novelty and its popularity at first stood in the way of its acceptance by educated people whose tastes were formed on the traditional arts. For some years after 1895, the year of the invention of motion picture projection, it was felt that because a film was the product of a complex mechanical process it could have little to do with artistic creation, while the fact that "the movies" appealed greatly to the lowest classes of society soon stamped them as vulgar. Eventually it was the very novelty of the film, the absence of a binding canon or tradition, which attracted artists from many other media and led to much constructive experiment. It was not, however, the "intellectual cinema" of the experimentalists, but the genuinely popular film, which developed into what we recognize as the art of the motion picture.

It was as a recording medium that the motion picture was first consciously used for "artistic" purposes. In France and Italy, famous players appeared in literal recordings of their customary theatrical vehicles during the years 1900-1911, and the results were applauded as a (somewhat inadequate) substitute for the stage. Meanwhile the popular film was developing a more original style. From 1909 to 1924, D. W. Griffith produced a series of important films in which he gradually evolved all the formal principles of the motion picture. These films, the most notable of which were *The Birth of A Nation* and *Intolerance,* disregarded the Aristotelian unities of the theatre (and indeed the spatial and temporal laws of every-day experience) in order to exploit the emotional and intellectual effects of the joining of two or more images related to one another solely by *theme.* Griffith's discoveries were immediately absorbed by film directors everywhere, and the *cut,* with its destruction of time and space, became the chief formal instrument of film construction throughout the world, and particularly in the American film (see cutting).

The influence of the other arts on the motion picture first became evident after World War I, and chiefly in continental Europe. Influenced in Germany by the expressionist theatre and in France by advance guard painting, experimenting film-makers produced many interesting films and a few of genuine cinematic merit. Though some of these films, notably *The Cabinet of Dr.*

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

*Caligari,* became world-famous, they were not widely shown and had small effect on the style and content of the popular film, though their producers were from time to time imported by Hollywood. In Russia, on the other hand, the Soviet directors of the 1920's made important contributions to the principles of cinematography. S. M. Eisenstein and V. I. Pudovkin closely studied the disjunctive style of Griffith, and co-ordinated his sometimes capricious and always instinctive methods into a reasoned film aesthetic. Films such as *Potemkin* (1925) and *Storm Over Asia* (1928) were particularly successful in exploiting the physical and psychological effects obtainable by "rate of cutting" (see cutting).

With the arrival of the sound film, 1926-28, the motion picture momentarily returned to its early task of recording plays, but within a few years began to resume the freer, more cinematic techniques of the silent era. As early as 1928, the Soviet film-makers had produced a theory of the sound film which incorporated all the principles of silent cinematography while suggesting an imaginative (as opposed to a literally reproductive) use of the sound factor (see SOUND, below). This theory has never been successfully realized even in Russia, and other potentialities remain to be fully explored. The technique of the great majority of sound films continues to represent a compromise between the principles discovered by Griffith and the methods of the theatre. But the range of film expression is slowly widening through experiments conducted both independently (e.g., in the documentary film) and within the film industry, especially in recent years. Though it can hardly be claimed that spectators in the mass actually *create* moving pictures, there can be little doubt that the film is the most popular of the modern arts—popular in content and form as well as in terms of the box-office. The organization of the film industry itself demands that each picture appeal to a vast undifferentiated audience and that it bring quick financial returns. This situation has resulted in the rise to power of individual producers and artists who "think like" their audiences and therefore reflect popular taste as much by instinct as by calculation. It is for this reason that the most important aesthetic consequence of the introduction of sound to the screen is now seen to be the development of a lively naturalistic style which readily reflects contemporary feelings, interests, and notions, and which confirms the position of the popular film as the dominant form of the cinema. —I.B.

**motor-constructive experience.** (art ed.). The phase of the art experience characteristic of the crafts and of industrial arts; used in art education to designate activities requiring muscular-mental coordination and involving the planning and building of objects through the use of materials and tools, as distinguished from such activities as drawing, painting, and similar forms of art expression; for example, designing and building a coffee table. Whitford and Winslow in *Dictionary of Education.*

**motto.** See HERALDRY.

**motu proprio.** See MEDIEVAL MUSIC.

**Mound Builders.** The theory that the Mound Builders were one people with a single coherent culture which preceded that of the American Indian is now abandoned. It has been proven that mounds were built by many prehistoric peoples of different cultures, scattered widely over the eastern half of the U. S. A.; that in some localities the culture which produced them disappeared before the coming of the Europeans; and that in some places the builders were the ancestors of the historical Indians. See Eastern North American Aboriginal Art. —H.G.

**mountain and water painting.** Chinese name for landscape painting. See CHINESE ARTS.

**mountain green.** See malachite.

**mountain-temples.** See SOUTHEASTERN ASIATIC ART.

**mourning ring.** See JEWELRY.

**mouthpiece.** See ACOUSTICS.

**movable altar.** See altar.

**movable Do.** The basis of a system in which the notes represented by syllable names relate to a tonic note or tone center, called "Do". The note to which Do is applied may be shifted from one tonal center to another (see modulation) in the course of a composition, hence the term, "movable Do". The term is likewise used in contradistinction to "fixed Do" the basis of a system common in France, Belgium, etc., in which the scale names do, re, me, etc., are applied to a fixed pitch. Do equals C, re, D, me, E,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

etc., and inflections of these syllables are employed for the various sharps and flats.

The movable Do system dates to the time of Guido (see solmization). The basis of the system is relative pitch in which each note bears a relation to the tonic or key note as well as to a note that precedes or follows it. Several systems have appeared giving a modern dress to the earlier one of Guido. The Tonic Sol-Fa method developed by John Curwen in England dates from the mid-19th cent. The Chevé method is similar but seeks to simplify matters by using numbers. Thus 1 equals do, 2, re, etc. Mention must be made of the Fa-Sol-la system used in singing white spirituals in the South, another variant of the movable Do idea.

There has been endless debate on the subject of the value of Movable and Fixed Do. That of Hullah and Curwen is historical. Both systems have their merits and defects although it is generally admitted that for beginners and for music that adheres to the diatonic line (Gregorian Chant, polyphony, etc.) the movable-Do system is the better. The Chevé method mentioned above is the basis of the Ward method so widely used in the United States today. —J.V.H.

**movement.** (1) *In dance,* movement is the medium of expression and the body is the instrumental means of its communication. By nature we are given a body constructed and designed for certain kinds of locomotion and body activity, whose combinations offer an infinite variety of postures, gestures, and actions. Its skeletal framework serves as a system of levers that not only support and give form to the body and its actions but also offers points of attachment for muscles. The joints determine the kinds of movement possible and set the mechanical limits for motor response. They depend, however, for their action upon muscle action whose potential energy is controlled and released by nerve impulse. Since a muscle is fastened to two bones it pulls them toward or away from each other or rotates them according to joint structure, thus causing a change of position producing movements of bending, stretching, twisting and the various forms of locomotion. So movement as observable behavior primarily originates in nerve and muscle action. When movement takes place, we can observe that **distance** is covered and **direction** taken. Movements may be confined to narrow limits or expanded to the fullest capacity of structure. They have **range.** Direction is the course of motion that establishes a space relation directly between the point of departure and the point of arrival, that is, movements have aim or **focus.** The actual path travelled may be direct or deviating. Movement, like sound, is a succession of intervals continuing in time and marking the passage of time. Movement intervals, therefore, have **duration**—which may be of varying lengths. This actual length is determined in the hidden principle of muscle and nerve action. Neuro-muscular action is manifested in movement intervals having duration and force because muscular action itself can only take place in alternate intervals of contraction and relaxation which are characterized by their duration and force of execution. Movement intervals, therefore, are also observed to have heavy or light **stress** or **force** according to the amount of muscle tension present in their performance. And finally, movement intervals may follow in slow or rapid pulsations. Movement has **speed** or rate of execution. No movement, however large or small, strong or weak, fast or slow, can take place unless range, speed, force, and space are involved.

These factors do not explain the activity within the mental life of the dancer. Meaningfulness in movement is determined by forces of another order. We are designed to think and feel as well as to move, therefore we cannot submit to mechanical laws alone. The anatomical and physiological equipment represent the more impersonal forces that are universally shared. They are ever present and active in all activity. The important issue is the individual use made of them. It is when movement is submitted to the dictates of an individual intellect and emotion that it ceases to be mechanical and becomes a manifestation of a unique and individual ordering. This unique ordering is determined by the psychological factors. They represent the personal endowments that through knowledge and use are the only forces that lend warmth and significance to any act. Within this mental equipment resides the awareness of all sensations as well as the capacity to think, feel, create, and will. It is the equipment for interpreting movement experience and creating its art expression in dance. Action implies a desire which prompts it, a thought which shapes it, and a visible movement of the physical body to carry it out. Two of these component activities are invisible and belong to the conscious-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

ness, but are revealed by the third component which is visible and belongs to the body. As outward observable behavior, movement is an integration of the physical and mental natures. In dance, movements become the motor symbols of actions within the mental life of the dancer (see rhythm, kinesthetic sense, and tension). (2) *Mus.* (a) Tempo, rate of speed. (b) One of the 3/4 parts of a sonata or symphony (qq.v.). —M.N. H'D.

**moving sculpture.** See SCULPTURE.

**Mozarabic architecture.** See SPAIN, ART OF.

**Mozarabic chant.** See MEDIEVAL MUSIC.

**mp.** See NOTATION.

**mudejar.** See Mexico, post-Conquest architecture of; SPANISH ARCHITECTURE IN THE NEW WORLD; FURNITURE.

**mudrā** (Skr.). A mystic gesture of the hands and fingers, of religious significance, which symbolizes certain functions of a deity. In oriental art it often identifies the deity. See abhaya mudrā; bhūmisparśa mudrā; dharmacakra mudrā; dhyāna mudra; samādhi mudrā; varada mudra; also *Buddhist Hand Symbols,* Aisaburo Akiyama, Yokohama, 1939; *The Gods of Northern Buddhism,* Alice Getty, 1928; *The Iconography of Tibetan Lamaism,* Antoinette K. Gordon, 1939. —J.A.M.

**muffle.** *Cer.* Compartment for firing ware by radiation. See CERAMICS I.

**Mughal art.** See INDIAN ART.

**mugharna** (Ar.). *Arch.* A stalactite decoration. See ISLAMIC ART.

**muller.** Traditionally used for grinding pigments on a slab, the muller is a rounded stone, flat at the bottom and moved over the slab by hand. A pigment mixed with oil or water is laid as a paste on the slab. Usually the muller is of the same material as the grinding surface, a hard stone like porphyry being the traditional preference. Modern hand grinding in the studio is usually done on glass slabs with glass mullers. See grinding slab. —G.L.S.

**mullion** (A corruption of the Fr. ***munnion,*** stump). A minor division-piece between window openings or window frames.

**mul sulkas.** See cotton.

**mummy pigment.** Composed largely of bitumen, this dull brown coloring material was taken from bones and bodily remains of Egyptian mummies in which bitumen or asphaltum had been used in the embalming process. It was used chiefly as an oil paint in the 17th to 19th cents. —G.L.S.

**muntin** (A corruption of the Fr. ***munnion,*** stump). A minor division-piece between window-lights, openings, or panels within the main frame or outline of the opening. —J.M.M.

**mural painting.** The decoration of walls, and by extension, of ceilings uses fresco, oil, or encaustic techniques. It excludes from consideration other forms of interior surface decoration such as relief sculpture, mosaic, marble encrustations, and panelling. Generally speaking, it is subordinated to the architectural surfaces it embellishes. However, such variant forms as the chalk drawings within incised outlines in the Pyrenees caves dating from the Reindeer Age and the frescos of the grottos of Ajanta in India, must be considered, as well as the Pompeian mode of painted architecture, Michelangelo's painted architecture and sculpturesque figures on the Sistine ceiling, and such baroque extravagances as Correggio's paintings at Parma and those of Balthasar Neumann at the Vierzehnheiligen church, light and space integrating with the major art forms.

In **fresco** the pigment mixed with water is applied to the plaster surface while it is still wet. The section completed by the time the plaster dries has become a permanent part of the wall, coated with a veil of carbonate of lime. The dried plaster still unpainted must be cut away before another day's work is begun. With the aid of full-sized cartoons the master or his apprentice transfers to the wall the section designed for that day's program, working rapidly and boldly with emphasis necessarily on only the main effects. Changes can be made only with tempera of limited permanence. The great masters of classical times and of the early Renaissance used this technique. In recent years experimentation in "**true fresco**" has been frequent.

In **tempera** the pigments, mixed with such binding material as white of egg, honey or gum, and water, are applied to a dry plaster surface. The chief danger of this technique is that of peeling, although it has the advantage of permitting changes during execution. It was much used in ancient times, by the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Egyptians, e.g., and frequently by modern artists.

In **encaustic** the wall surface is prepared with wax, tempera pigments are used, and after the painting is finished, the surface is covered with wax, or the pigments may be mixed with melted wax on a hot palette. The Romans used it on occasion for details, and it has been revived in modern times.

**Oil painting** uses linseed oil as the binding medium and turpentine as dryer. The advantages of this technique are that it permits the completion of the painting in the studio, it is suitable for wood, copper, or canvas surfaces, and it maintains lustrous color values. On the other hand, when the canvas is applied to the wall, with white lead and oil as adhesives, it may create a different effect from the one in the studio, and it has little permanence if the wall is subjected to dampness. Even when mounted on a stretcher the colors may darken with age and the canvas disintegrate. However, it was used with great success by the Venetian masters, and is the common method of modern mural painters. Leonardo's *Last Supper* used oil on a surface badly prepared for it and disastrous flaking has resulted.

The major problems of the mural painter center on whether his design shall ignore or integrate with or remain subordinate to the flat surface. The answer of history seems to be that the burden of proof is with the artist. The problem is essentially one of the character of the setting, its use, and the intention of the artist. Regardless of the "integrity of the wall" decorative force, monumental composition, and thrilling beauty may be achieved, as channels through which experience may be transferred with enriching results. Thus the Egyptian in his tomb painting followed such conventions as overlapping and superposition to indicate space, keeping his outlines incisive and his colors flat and conventional. The Greeks and the Romans moved in the direction of modelling and atmospheric gradations to suggest space, but also had a repertory of purely ornamental forms for decorative use. The medieval European mural painter kept his modelling on a front plane and by simplification or distortion often underscored its meaning in other than plastic senses, meanwhile keeping the background inactive. The frescos of the Horiuji Temple, Nara, Japan, with their Chinese-Greco-Buddhist characteristics, illustrate the use of "ideal" space in harmonic relationships with meaningful line and decorative color. Realization of the objective world, controlled to some extent within architectural frames and on occasion re-created in a world of plastic reality, was sought by the Italian masters of the Renaissance from Giotto (with his still Gothic palette and strong feeling for structural relations of line and form) to Uccello with his use of vanishing-point perspective, Masaccio with his aerial perspective, and the Venetians with their chromatic perspective. In them all space was controlled, but expressively used. Piero della Francesco, Raphael, Titian, Veronese, and Tintoretto in Italy and Rubens in the North achieved high success in this creation of a world of decorative reality.

Throughout the baroque and rococo periods mural painting was either accompanied by or subordinated to other types of decorations and did not reach its modern development perhaps until Puvis de Chavannes in the 19th cent. applied Giottesque principals in the Pantheon in Paris. In America the revival is connected with John La Farge and his Trinity Church frescos in Boston, his notable *Ascension* lunette in the church of the same name in New York, and with the World's Fair in Chicago in 1893 where a large number of young painters had a chance to learn the technique. The Boston Public Library, with work by J. S. Sargent, E. A. Abbey, and Puvis de Chavannes, and the Library of Congress in Washington were also useful laboratories. Perhaps future generations will agree that the most significant factor in the development of mural painting in America was the government-sponsored projects in the 30's wherein both beginners and experienced artists were commissioned to decorate with murals public buildings in Washington and throughout the country. In a literal sense this movement has initiated a renaissance of interest in mural painting. Meanwhile in Mexico and in Brazil the technique of Europe and the heritage of Indian and Negro are finding brilliant expression on walls as Orozco, Rivera, and Siqueiros on the one hand, and Portinari on the other, reveal once more the fundamental power of mural painting. **muscle sense.** See kinesthetic sense.

**MUSEUM.** (L. *museum,* fm. the Gr. *mouseion,* temple of the Muses, fm. *Mousa,* muse). Museums are established for preservation, study, and exhibition of original objects as they come from nature and from the hand of man, the maker. To interpret the significance of these objects and to demonstrate their meaning for the education of the people, museums make use of reproductions and other representative devices, restorations, rearrangements, charts, photographs, and the spoken and written word, along with the display of the objects themselves. The objects are assembled in collections classified by various categories and obtained through acquisition by purchase, gift, and bequest and through exploration and excavation.

Quantities of study material such as might go to a museum in modern times were sent from conquered lands to Aristotle by Alexander the Great; but Aristotle apparently used them up; at any rate they were not preserved through the ages. Other early collections suffered the same fate; man has always been a collector of objects, but only in comparatively recent times have these objects been preserved in museums. Ptolemy Soter, under the inspiration of Alexander's Hellenizing policy, founded the museum at Alexandria in Egypt, but that was essentially a library and academy of advanced study. The ancient Romans showed trophies of conquest in the capital and the medieval church preserved ecclesiastical relics; but the first were ephemeral displays and the second were religious treasures to be venerated as such, not objective examples of the work of man or nature.

It was not until the 15th cent. that a continuous history of the preservation and development of collections began, leading up in subsequent periods to the establishment of the museum as an institution of public significance. The discovery of America and the rediscovery of the ancient Greek and Roman civilizations so stimulated the formation of collections that kings, princes, and nobles vied with each other in accumulating objects of classical art; and scholars and men of wealth assembled specimens of minerals, plants, and animals brought by explorers and traders from distant lands. There grew up during the next two centuries throughout Europe art collections, coin and medal collections, natural history collections, and collections in which all three of these were intermingled with mere curiosities. The materials thus assembled, many of them persisting as state collections, formed the nucleus of museums; for instance, Cosimo de Medici's collections, now in the Florentine galleries; the Kunst and Naturalien Kammer of Augustus, Elector of Saxony, that led to the formation of the muesums of Dresden; and the collections of Francis I and his successors that went into the Louvre.

The museum as a public institution was the creation of the 18th cent. The first of its kind that was called a museum, the Ashmolean Museum at Oxford University, came into being shortly before the opening of the century, in 1683. In that year the university erected a building to house the collection assembled by John Tradescent and given by Elias Ashmole, with other material of his own collecting, to the university. Between 1740 and 1745 Pope Benedict XIV founded the first Christian museum in the Vatican. In 1753 Sir Hans Sloan's collections were accepted by the Parliament of Great Britain for the establishment of the British Museum. The first American museum was organized in 1773 at Charleston, South Carolina, as the Charleston Museum. The Museo Nacional de Ciencias Naturales at Madrid, established by royal decree in 1771, was opened to the public in 1776. At Paris in 1793 the Muséum de la République (now Musée Nationale du Louvre) was constituted at the Louvre and the next year the Jardin du Roi became the Muséum National d'Histoire Naturelle. By the close of the century the museum was firmly established and was recognized by the state and the public for its service in the preservation of valuable materials. Its growth, however, was inward; its chief impulse was to attract further accumulations of material and to hold its collections subject to study by those who actively sought admittance; it made no attempt to attract visitors or to reach out beyond its walls to educate the general public.

In the 19th cent. the museum reached its maturity. The palace collection, the cabinet of the prince or scholar, the public depository, the formative stages, gave way to the modern museum, a laboratory of research and a center of public education. Before that time the pattern had been: in art museums, solid galleries of painting or sculpture; in

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

science museums, specimens arranged in rows or cases in regular order. About mid-century, educational exhibits, as distinguished from exhibits that were only collections, were first installed in museums. In 1844, the Musée de Cluny was opened with craft work of the Middle Ages arranged by period; the first museum group in science in the U. S. A. was shown in New York in 1869 and had its origin in England a few years earlier. The Great Exhibition at the Crystal Palace in London in 1851 led to the establishment the next year of the first industrial art museum at South Kensington in which craft work was arranged by material in departments of woodwork, metal, textiles, pottery, and glass, and which became a source for design ideas for handicrafts first and later for machine articles, the early inartistic character of which had been exposed by the Crystal Palace exhibition. The Nuremberg museum in 1888 introduced period rooms with appropriate settings. Museums had begun to make a selection of their material for display and to house the rest of the collections separately in systematic order for the use of research and scholarship. They began to seek the attention of the general public by more flexible arrangements, changing exhibits, and other devices; and finally they extended their efforts outside the museum walls, to the schools and to the community as a whole.

By assembling large groups of material calculated to attract the wonder and curiosity of the people, by directing attention to scientific, artistic, and industrial developments, and by demonstrating the effectiveness of visual education, the international expositions of the time exerted a powerful influence on the museum movement of the 19th cent. and after. Besides the South Kensington museum, institutions directly attributable to the influence of expositions include the Ethnological Museum at the Trocadero, Paris exposition 1878; Field Museum of Natural History, Chicago exposition 1893; Museum of Science and Industry, Chicago exposition 1933; City Art Museum of St. Louis, St. Louis exposition 1904; San Diego Natural History Museum, exposition of 1915. The centennial exposition at Philadelphia in 1876 led to the construction of a building for the U. S. National Museum at Washington, and one of its buildings, Memorial Hall, is a part of the Philadelphia Museum of Art.

Early in the 20th cent., in the interval between World War I and World War II, museums established themselves throughout the world as recognized centers for the advancement of civilization. By the early 1930's new museums were being established in the U. S. A. at the rate of about two a week. Soviet Russia was setting up new museums in many communities not heretofore having stable cultural centers, many of these being intended as visual instruction texts for a population anxious to make up in as short a time as possible the inadequacies of schooling during the Tsarist regime. The republican government of China fostered the establishment of museums, of which some 100 or more were in operation at the time of the Japanese attack. In other parts of the world the museum influence grew more slowly but none the less steadily. Estimates during the early stages of this development put the number of museums in the U. S. A. and Germany at about 1,500 each, Great Britain and France about 600 each, Italy 400, Russia 200, Australia and New Zealand 160, Japan 160, Canada 125, China 100, South America 100, Mexico and the West Indies 75, Africa 60. The world total was somewhere in the neighborhood of 7,000.

The U. S. A., continuing to establish museums rapidly, had outstripped all other countries, with 2,500 museums of all kinds, at the time of the most recent comprehensive study, completed at the close of 1938 (L. V. Coleman, *The Museum in America,* 1939, Washington). In this study 387 museums that included art in their field were listed. Of these 224 were public museums, including 47 art centers sponsored by the Federal Government under the relief program. Since this survey several notable art museums have been opened, the most important being the National Gallery of Art at Washington, March 17, 1941. Other new art museums are the Museum of Modern Art, New York, 1939; the Fisher Art Gallery of the University of Southern California, Los Angeles, 1940; the Norton Gallery and School of Art, West Palm Beach, 1941; and the Santa Barbara Museum of Art, 1941. There are 1300 history museums, 700 science museums, 130 general museums, and 30 industry museums.

Public art museums in the U. S. A. (1866-1938) accumulated an investment of $83,154,000 in buildings designed for museum use. College art museums added another $6,576,000. Museum buildings of all kinds, constructed for museum use, represented an investment of $181,312,000. The largest single addition to these totals since 1938 was the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

construction of the National Gallery of Art, built at a cost of $15,000,000.

Early museum buildings were structures built for other purposes, mostly palaces or other abodes of the powerful and wealthy. Such persist to this day and in Europe they are still dominant in the scene of national and provincial institutions. In America most great public museums occupy buildings constructed for museum or exhibition use; old buildings converted from other uses are mostly the result of budgetary restrictions on new institutions or institutions that have not been able to accumulate the funds necessary to construct better quarters. In the U. S. A. the classical revival gave the form of ancient monuments to early buildings constructed for museum use, as it did to public buildings generally. Thus the first public museum building, Pilgrim Hall of the Pilgrim Society at Plymouth, was built in the form of a Greek temple. Palace designs in the style of the Renaissance were adopted in the middle 19th cent. and had the advantage of providing suites of rooms that opened one into another and disadvantage of ornate interiors. Even after the "architectural interior" became a thing of the past, near-Renaissance façades continued to be built. In the present century American Colonial styles, Gregorian in the East and Spanish in the West, began to be used. Functional elements increased as time went on in the interior of all these buildings—well studied arrangements of rooms for display, differentiation of parts of the building to provide for such developments as the period room and the habitat group, and provision for work space and space for the study collections. Since World War I museum buildings have begun to appear with functional requirements stressed both in exterior design and interior arrangement; e.g.,the Henry Art Gallery of the University of Washington, Seattle (1927), Colorado Springs Fine Arts Center (1936), Museum of Modern Art, New York (1939), Grand Rapids Public Museum (1940). The Grand Rapids Public Museum embodies such up-to-date ideas as street show windows, entrance and first floor at sidewalk level, complete artificial lighting of exhibit halls, air conditioning through the building, curtain partitions, radio and public address system reaching all halls, and a large central exhibit hall into which light trucks may be driven for loading and unloading material for frequent changing exhibits. Two new types of museums of the last two decades have their own special style of building: the trailside museum, which is a simple structure planned to conform to the natural site on which it is placed; and the planetarium built in the modified form of an observatory for the housing of a Zeiss projector and for related exhibits on astronomy.

Modern museums have widened their fields in many directions. The art museum, formerly confined to the graphic and plastic arts, now embraces practically all phases of creative art. The art museum of today may concern itself with decorative arts, music, the dance, the drama, and the film; the history museum with the city in which it is located, as a huge exhibit to be studied in place; the science museum, with the health of man and his heredity and psychology. Special museums are provided for the education of children, for the visitor to parks and trailsides, and for the instruction of the public in many aspects of science and technology.

Educational work is recognized in American museums as a primary activity and takes many forms: exhibitions (q.v.), of both permanent collections and changing material on loan; guidance of visitors through the halls and galleries; lectures, courses, concerts, and other performances in the museum for adults and for children; creative work; printed material; work with the schools and with other organizations in and out of the museum; special rooms, classes, and other activities for children; and prepared extension material for the use of schools, colleges, and universities and for general distribution to civilian and military organizations. Many of these activities have been on the program for a long time. They have, however, increased steadily through the past fifty years and they have been encouraged by fundamental research in museum education and exhibit problems beginning at the Art Institute of Chicago in 1925 under direction of Edward S. Robinson. These investigations, supported by grants from the Carnegie Corporation of New York to the American Association of Museums and to Yale University, were continued by Dr. Robinson and his associations until his death in 1937 and then by his associates and others. Studies in museum education were undertaken at the Philadelphia Museum of Art, Buffalo Museum of Science, New York Museum of Science and Industry, the Carnegie Institute of Pittsburgh, Newark Museum, and the 69th Street Branch of the Philadelphia Museum of Art. A separate study of work with grade school children

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

was conducted by Margaret Bloomberg at the Cleveland Museum of Art and published in 1929. Recently a grant from the General Education Board of the Rockefeller Foundation has supported a series of studies of work with secondary schools at the Art Institute of Chicago, Museum of Modern Art, Albright Art Gallery, Milwaukee Art Institute, and Cleveland Museum of Art, begun in 1939 and just now being prepared for publication. Every large art and science museum in the country has established a departmental staff charged with carrying on and developing to its utmost the educational effort. The smaller museums give much of the time of staff members to the work. In St. Louis and Indianapolis special museums have been established by the public school systems with the direct duty of supplying the schools with opportunities for the study of museum material. Museums in New York and Boston have established intermuseum councils, the principal object of which is cooperation in extending and making more effective the educational work of museums on behalf of their communities.

The active character of the modern museum is esp. well illustrated in the manner in which it has sought out ways and means of supporting the morale of the armed forces as well as the civilian in the war crisis. Special programs for the armed forces have been organized in the museum halls, exhibitions have been sent out to the camps and recreation halls, musical material has been distributed to service musical organizations and song books to the individual soldier and sailor, facilities and material have been provided for soldier artists in camps, and the talents of American artists have been utilized through the museum for therapeutic work among disabled soldiers and sailors. On the side of civilian morale there have been exhibitions of methods of civilian camouflage, of material illustrating the war areas, of films and programs to acquaint the public with the problems and the aims of the war production effort.

A list of the important museums in America would be too long to include in this essay. A few of them are the following: For art, the National Gallery of Art, Washington; Metropolitan Museum of Art, New York; Philadelphia Museum of Art; Museum of Fine Arts, Boston; Art Institute of Chicago. For science, the U. S. National Museum, Washington; American Museum of Natural History, New York; Chicago Natural History Museum, Chicago. For history, New York Historical Society, Chicago Historical Society, Museum of the City of New York, Edison Institute, Dearborn. For industry, Franklin Institute, Philadelphia; Museum of Science and Industry, Chicago. For general museums, U. S. National Museum, Washington; Newark Museum, Milwaukee Public Museum, Rochester Museum of the Arts and Sciences. See L. V. Coleman, *The Museum in America,* 1939, Washington; David Murray, *Museums: Their History and Their Use,* 3 vols., 1904, Glasgow; William Flower, *Essays on Museums,* 1896, London; *Handbook of American Museums,* 1932, Washington; *Directory of Museums and Art Galleries in the British Isles,* 1931, London; *Maecenas,* 1930, Berlin, *Mouseion,* International Museums Office, Paris, 1927-1940, triannually; *The Museum Journal,* London, monthly; *The Museum News,* Washington, semi-monthly. —L.C.E.

**Mushiake yaki** (Jap.). Pottery made in Bizen province.

**musica ancilla religiosis.** See MUSICAL PERFORMANCE, MAIN TRENDS IN.

**musica ficta, falsa.** Literally false music, i.e., altered tones not included in the ecclesiastical modes (q.v.). In the words of the author of the early 14th cent. treatise, *Ars Contrapuncti,* "Music is called *ficta* when we make a tone to be a semi-tone, or, conversely, a semi-tone to be a tone". Composers did not indicate the chromatic alterations, since it was customary to rely on the singer's judgment. For the modern transcriber, the difficulties involved in musica ficta are sometimes almost insuperable, especially since there is considerable disparity of statement among the old theorists as to the rules of interpretation. Nevertheless, some rules were simple enough. The correction of the augmented 4th and its inversion the diminished 5th both melodically and harmonically was accomplished by alteration. Cadential progressions which engendered the feeling of the "leading tone" (q.v.) usually required an adjustment in the penultimate chord. Musica ficta was undoubtedly the greatest single factor which led to the gradual obliteration of the ecclesiastical modes. In modern editions of medieval music, transcribers usually indicate the altered tones by the appropriate accidentals over the notes. See NOTATION; scales and modes. —V.A.

**musical glasses.** See MUSICAL INSTRUMENTS.

**musical imagery.** See EXPERIMENTAL PSYCHOLOGY OF MUSIC.

MUSICAL INSTRUMENTS. *I. The Development of Musical Instruments.* The evolution of musical instruments proceeds from two basic roots. One is the human tendency to express emotion through periodic motor activity. Thus most primitive instruments are to be regarded as audible reinforcements of bodily movements. Man stamped on a bark covered cavity instead of on the bare ground, made the movement of the forearm audible by waving a **rattle.** Another outlet was the expression of emotion by sounds of more or less definite pitch. Here the voice with its freedom of inflection was the most efficient means. Much technical skill was needed to construct instruments which would produce a series of musical tones. Primitive instruments were used to produce terrifying and supernatural sounds with magic power rather than pleasing and musical tones. Many early instruments were constructed in pairs as is shown by the strange twin pipes and trumpets. The organization of similar units of different vibrating lengths and hence different pitches marks a more advanced stage of development. Thus bamboo tubes of various lengths were bound together to become the **panpipes** and vibrating bars of wood were arranged in a series to become the **xylophone.**

Less obvious were the possibilities of a vibrating air column within a **flute** or **horn.** Players passed from the stage where the performer sang or shouted into a horn to the stage in which the lips vibrated against a mouth hole or **cupped mouthpiece** to produce one harsh sound, then two, and eventually the harmonic series into which a vibrating air column naturally divides. Another basic discovery was the artificial shortening of the air column by **fingerholes** pierced in the wall of cane flute or animal horn which could be opened or closed **at will.**

With stringed instruments also tones of varied pitch could be produced in various ways. Strings may be arranged in a series varying in length (and frequently in thickness as well) as in the harp or piano. The player might pull the string tighter to raise the pitch as the **ānanda laharī** of Bengal. A string might be effectively shortened and the pitch raised by being pressed down against a fingerboard with the finger; or, if lightly touched with finger or nail, it would produce tones of a more flute-like character called harmonics (q.v.).

The growing complexity of musical instruments eventually reached the point where a special craft developed to conserve and to practise the skills required. One result was a greater uniformity among instruments since a given workman or atélier was likely to make only certain types and sizes. The machine technics of the 19th cent. had a profound effect on the manufacture of instruments as did the principles of mass production. Even cheap violins are mass produced though the finer violins have always been made and repaired by highly skilled artist craftsmen. Such an elaborate musical machine as the Boehm flute is hardly conceivable except as a product of the machine age. As a result of the mass production of musical instruments which are sold at a moderate price, instrumental music has been brought more nearly within the reach of school children and music lovers of moderate income.

*II. The Classification of Musical Instruments.* The more detailed discussion of musical instruments which follows is organized according to the following plan.

a. Sonorous substances
b. Vibrating membranes
c. Vibrating air columns
    1. Horns and trumpets
    2. Pipes
d. Vibrating strings
e. Electro-musical instruments

*III. Sonorous Substances.* Substances which resound when stamped, shaken, struck, scraped, or rubbed are so varied, so available and so numerous as to render more than a summary account impossible. Pounding with the end of a heavy stick is obviously similar to

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

stamping with the feet. Thus the hollowed and longitudinally slotted instruments of wood called **slit drums** are at one stage sounded by stamping feet, at another by the end of a heavy stick and finally are played in modern style by being struck at the edge of the slot by a pair of drum sticks. In a similar fashion the **stamping tube**, a length of bamboo stopped at the upper end, is struck against the ground producing a sound of vague pitch. Two or three tubes are sometimes employed with contrasting tones.

The rattle is familiar as a baby's toy and as the **maraca** of Latin-American dance orchestras. It is a very ancient device and may be a rattling string of teeth, claws or the like, a hollow body of tortoise shell, basketry, clay, or perhaps a gourd containing small stones or similar objects, usually grasped by a handle.

Instruments which are sounded by percussion are frequently employed in pairs. Such are the percussion sticks, recent forms of which are the "**bones**" of the American negro, the ***maracas*** of the rhumba band, the **castanets** of the Spanish dancer. **Cymbals**, plate shaped discs of hammered bronze with a central boss, are usually clashed together as pairs but in modern practice a single cymbal is frequently struck with a drum stick. This relationship of beating stick and sonorous object is also characteristic of the **triangle** (a vibrating steel rod bent in the shape suggested by its name), the ominous sounding **gong** (a large circular bronze disc with the edges turned over), as well as the array of sonorous stone slabs, bells, and metal bars, often arranged as a series, which are so characteristic of Chinese, Javanese, and Balinese music and which reappear in the modern **glockenspiel**, the **xylophone**, the **marimba**, and the **celesta** (with keyboard).

Scraping as a method of producing sound seems to be chiefly confined to primitive rites. Notched bones, sticks or other substances are scraped by another hard object. A later offshoot of this primitive device is the carved **wooden tiger** (yü) with notched backbone which is sounded twice at the close of the Confucian rites. In a similar fashion Negroes in the southern part of the U.S.A. used to draw a key over the teeth of a horse's jawbone.

Even more specialized is the **kulepa** of New Ireland (Melanesia). A rounded wooden block is deeply cut so as to divide it into four segments varying in size which produce four corresponding tones when rubbed by the moistened hands. This principle reappears in the European **musical glasses** or **glass harmonica** which produce pure and ethereal tones when the rims are rubbed by the moistened fingers.

*IV. Vibrating membranes.* The **drum** consists of one or two skins stretched over a frame or the opening of a hollow body. Modern Western civilization is relatively poor in these instruments which are so varied among primitive peoples. The body of the drum may be a tree trunk hollowed by tools or fire. A drum shaped like a barrel and with two heads is frequent in the East. As drums became smaller and hence portable their forms reflect this fact. The wine glass form can easily be carried under the arm. Drums expanding above and below a central waist and provided with two handles are even more clearly designed to be carried. Somewhat similar in form are the **hourglass** and **spool drums** of the Far East. India developed sets of tuned drums, pairs, sets of three, and finally in Burma a circle of as many as twenty-four drums on which melodies were played.

In contrast to the relatively deep drums described above are the shallow drums with one or two heads stretched over a wooden rim of greater or less depth. The modern **tambourine** is a familiar example of one type. In addition to the tambourine type (with one or two heads) we may distinguish the **shaman's drum** as another type, a shallow one-headed frame drum, carried either by a handle projecting from the frame, by cords passing across the open back of the drum, or by a wooden brace passing from side to side of the frame.

In Europe the use of the drum seems to date from the 12th cent. The drum was played with the left hand and was associated with a horn or pipe played by the other hand. After the Crusades double headed **army drums** played with two sticks appeared and were associated with the fife. **Kettledrums** were imported from the Near East, the smaller forms in the 13th cent., the larger type in the 15th cent. Thus the kettle drum of the modern orchestra made an early entrance into Europe. The use of screws to adjust the heads is illustrated in Virdung (1518). The modern **snare drum** is smaller and shallower. The shell is of wood or metal and the rattling gut snares under the lower head are replaced by coiled wire springs. The heads are tightened by metal rods with adjustable screws. The **bass drum** was part of the Janissary or Turkish military music, associated with tri-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

angles and cymbals. Haydn's *Military Symphony* shows these instruments used for local color; they later become regular constituents of the orchestra.

*V. Vibrating air column.* 1. THE FLUTES. We must distinguish the recorder, the end blown flute, and the side blown or transverse flute.

In the **flageolet** or **recorder** the stream of air passes through a directive channel (languid) against a sharp beveled lip cut in the body of the instrument. The tube is provided with finger holes, and thumbhole in back.

In the **end blown flute** the stream of air is directed against the sharp outer edge of the open top of the tube which is also sometimes notched. The **nose flute** is similar but is blown by breath from the right nostril the left being closed.

In the **side blown** or **transverse flute** the player blows across a sharp edged mouth hole. The hole is held horizontally (or nearly so) and the upper end of the tube is closed with a cork or stopper. The previously cylindrical European flute was made with a conical bore and cylindrical head joint in the latter half of the 17th cent. During the same period a single key was added which produced d sharp. Keys for the other chromatic tones were gradually added. The body of the **Boehm flute** is cylindrical, the head parabolic in bore. The large circular holes are covered by large pads controlled by an elaborately devised key mechanism. The little **octave flute** or **piccolo** is the only other flute used regularly in the symphony orchestra; the **alto** (**flute d'amour**) and **bass flutes** are little used.

2. THE OBOES. The **oboe** group is played by a double reed which in the simplest instruments is merely a straw pinched together at the end and in later instruments consists of two opposing slips of cane bound together. Egyptian oboes were played in pairs (drone and melody), Greek oboes were also paired and were made in a variety of types. A leather mouth band (***phorbeia***) was employed, suggesting a rather violent manner of performance. Similar paired oboes appear in the East.

Renaissance oboes were called **shawns** and were built in families of seven. The **bassoon** (**curtal**) of this period was also a double reed instrument, conical in bore, with the tube doubled on itself and the reed carried on a tube extending from the body. The complete family of bassoons consisted of five instruments. In the modern orchestra the bassoon survives only as bass together with the still lower **double bassoon.** Similarly the oboe family is now represented only by the oboe and its alto form, the **English horn** (the baritone **Heckelphon** has been little used) though other forms are required in the scores of Bach (**oboe d'amore** and **oboe da caccia**). The obsolete double reed instruments can only be named here; the **bassanello,** the **sordone,** the **racket,** the **cromorne,** and the **Rauschpfeife.**

3. THE CLARINET. The **clarinet** is sounded with a single reed which in the simplest forms was simply a vibrating tongue detached from the cane which also formed the tube of the instrument. The ancient Egyptian clarinet which still survives in the Mohammedan East was a twin clarinet. Both pipes were fingered at the same time, but small differences in the two tubes produced an undulating tone. The Indian snake charmer uses a similar instrument save that the player blows into a gourd which encloses the upper end of the tubes. One of the pipes of this instrument functions as a drone.

In Europe the early history of the clarinet is obscure. The ***chalumeau*** was the European folk clarinet which was manufactured in an improved form by J. C. Denner of Nuremberg towards the end of the 17th cent. The modern clarinet with its cylindrical bore overblows at the twelfth, unlike the oboe and flute which overblow at the octave. Its beaked mouthpiece has a flat surface pierced by an opening against which the reed is secured. Made originally in the keys of C, A, and Bb the latter form is now favored. The **bass clarinet** is frequently employed in the modern symphony orchestra. The **alto** or **tenor clarinet** has remained a band instrument. The older **basset-horn** (employed by Mozart) was also an alto with a more extended lower range and a bore of smaller diameter.

The **saxophone** family is a hybrid group invented by the French inventor and instrument maker Sax. It has the form of an old fashioned Dutch pipe. The instrument is of brass with a clarinet mouthpiece but overblowing at the octave and fingered like the oboe. It has become identified with the swing band though scored for in certain symphonic works.

The union of the reed pipe with an air chamber in the form of a skin bag which is blown either by the mouth or by a small bellows, forms the **bagpipe.** The instrument is ancient. Pipes of both oboe and clarinet

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

type have been employed and the use of a drone is frequent.

4. THE ORGAN. The association of the keyboard with a series of pipes which are supplied with air by a bellows constitutes the **organ.** The Roman ***hydraulis*** which sounded pipes by air compressed by an enclosed body of water was outside the main line of development. The ***portative*** with flue pipes (pipes of metal or other material sounding by means of a stream of air directed against the lip as in the recorder) had a single bellows and was supported by a band. It was frequent in the Middle Ages and was pumped by the left fingered with the right hand. Pneumatic organs date from the end of the 4th cent. The pipes were first controlled by slides, later by levers, and finally by keys. All pipes connected with a given key sounded together. The Renaissance developed the possibility of selecting and combining the stops (a series of pipes, also the knob controlling that series) for a piece, the use of solo stops imitating wind instruments, and the possibility of using them singly. A limited pedal keyboard with its own stops appeared in certain cases. The **regal** was a small organ with reed pipes only.

The subsequent development of the organ has given the organist a more facile control of the keyboards (in four manual instruments called Great, Choir, Swell, Solo) through the evolution of the mechanical tracker action and the various pneumatic and electro-pneumatic actions. In the two latter types the organist simply sets in motion automatic agencies which perform the work formerly performed by the finger. The control of volume through the opening or closing of the shutters of the swell box (which encloses the pipes controlled by the swell keyboard) as well as the mechanical addition of stops by the crescendo pedal were inventions of later date as were the combinations, which made it possible to withdraw or retire selected groups of stops by merely pressing a button. The tendency toward tone of an orchestral type and towards organs of great size supplied with wind under high pressure has been countered by a recent trend towards the restoration of the **baroque organ,** a tendency which grew out of the interest in the organ works of Bach and his predecessors.

5. INSTRUMENTS WITH A FREE REED. The free reed of the **harmonium** and **reed organ** is similar to that in the Chinese ***shêng,*** an instrument of subdued and pleasant tone which resembles a tea pot filled with bamboo pipes of varying length. The reed here is a metal tongue vibrating in the aperture of its frame. The reed itself, not the length of the bamboo tube, determines the pitch of the tone produced. Such keyboard instruments as the **harmonium** and **reed organ** as well as the **concertina,** and **accordion,** and the humble **mouth-organ** or **harmonica** (so amazingly exploited at the present day) are all recent derivatives of the Chinese instrument.

6. HORNS AND TRUMPETS. In the **horn** and **trumpet** group the lips of the player vibrate into the hollow cavity of the mouthpiece. In its typical development the horn is related to an actual animal's horn while the trumpet form is thinner, suggesting a tube of wood or bark often curving outwards rather abruptly at the end into the bell. Certain specimens consist of a tube terminating with a cow's horn as a bell. Other early instruments of this group were **conch shells,** end or side blown, and **clay trumpets** (sometimes imitated from the shell form). A distinctive African form was the side blown elephant's tusk or antelope horn. The ***shofar,*** blown in all Jewish synagogues on New Year's Day and the Day of Atonement, is esp. notable as a very ancient instrument which has survived to the present day. It is made of a ram's horn, flattened and rather sharply bent at the end. An ancient form of curved horn was the Nordic ***lur,*** fashioned of cast bronze. The *lur* was constructed in pairs in which the S curves are opposite, suggesting that early examples were made from mammoth tusks.

In addition to a straight trumpet (Greek ***salpinx,*** Roman ***tuba***) which seems to have been played with considerable lip pressure to produce a terrifying sound, the Romans also had a straight trumpet with a bell turning up sharply at the end, the ***lituus.*** In the ***cornu*** the tube made almost a complete turn. A wooden rod passing from one side to the other supported the instrument high on the performer's shoulder, the bell pointing forward while the tube passed around the body. The mouthpiece was held to the lips of the player by the right hand while the left grasped the supporting rod.

Early European trumpets obviously have Eastern and Roman origins. The end blown ivory **oliphant** is similar to the African trumpets mentioned above, save that the African instruments are typically side blown. Other instruments are very similar to the Roman tuba. Trumpets developed in two models, the higher **tubecta** or **trombetta,** the lower ***buisine*** (Fr.) or ***Busine*** (Ger.).

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

The simple animal horn with fingerholes which appeared as early as 700 A.D. in Persia still survives as a pastoral instrument in Sweden, Norway, and elsewhere. This is the prototype of the **cornet** (in the older meaning of this word). The cornet (***cornetto curvo***) though made of wood or ivory, still mimics the contours of an animal horn. A straight form (***cornetto diritto***) existed, also the **mute cornet** (***cornetto muto***) with the mouthpiece excavated in the upper end of the body. The finger holes were six in number with an added key in later models. The cornet was capable of florid passages and of all the ornaments of the virtuoso singer, but was difficult to blow. In the 17th cent. the instrument was constructed in three sizes. The **serpent**, bent into deep curves, served as bass to the brass instruments till replaced by a form resembling the bassoon, the **Russian bassoon**, and the **ophicleide** or keyed serpent.

The special feature of the **trombone** consists of a U shaped slide which telescopes into the body of the instrument. The player can alter the sounding length of the tube by extending or retracting the slide and at each position can produce the various notes of the harmonic series. The instrument was constructed in three sizes, alto, tenor, and bass, towards the end of the 15th cent. **Contra bass** and **soprano trombones** were introduced in the 17th cent., but were never in common use. The trombone was hardly susceptible of real improvement. The military trumpet and the hunting horn, however, were limited in their early orchestral use by the fact that they could only produce the notes of the harmonic series. An attempt to bridge the gaps between the lower harmonics by applying padded keys to the body of the instrument resulted in such instruments as the **keyed bugle.** Various makers experimented with valves which added auxiliary tubes to the instrument. The imperfectly described twin trumpet with valve of Charles Clagget (described in 1793) appears to be the earliest attempt. In a modern instrument three valves, used singly or in combination, lower the pitch by a half tone, a tone or a tone and a half. These harmonic series when combined produce the complete chromatic scale. The system was not only applied to the horn and trumpet (and even the trombone) but to a new brass group, the **saxhorns.** The bass saxhorn appears in the orchestra as the tuba while the entire group forms a choir of the military band. The cornet employed by 19th cent. French composers in place of or with the orchestral trumpet is now used only in the band.

*VI. Vibrating Strings.* 1. PRIMITIVE INSTRUMENTS. The most primitive stringed instruments were huge affairs in which the resonating chamber was a pit dug in the ground. A sheet of bark which covered the hole served as a sounding board. There were two methods of keeping the string taut. In the **ground harp** one end is attached to the sounding board, the other to the free end of a bent green stick the lower end of which is fixed firmly in the ground. The player can produce notes of lower pitch by bending the stick still more. Later the instrument becomes smaller and self contained so that it can be carried about. In the **ground psaltery** the main string (thirteen to fourteen feet long) is fastened horizontally between two posts. A shorter string runs from the sounding board to the longer string, dividing the latter into two vibrating segments which accordingly produce two different tones. In later versions several such units are set up side by side.

The **musical bow** resembles the hunter's bow. The feeble tone of this instrument demands a resonator of some sort which is variously provided by a bowl, basket, pot, or metal vessel on which the bow is rested, by an attached gourd, or by the variable resonance of the mouth cavity of the player. This last method of obtaining resonance is still used in playing the **jew's-harp.**

Later stringed instruments may be broadly classified as psalteries, lutes, lyres, and harps. In the psaltery the strings pass from one end to the other of the supporting body. This type not only includes the psaltery and dulcimer but leads to the harpsichord and piano.

In the lutes a more or less extended neck emerges from a hemispherical body. The strings are shortened and raised in pitch by pressing them against the neck or by touching them lightly with the finger or the finger nail. In more recent instruments the body, instead of resembling a halved pear, becomes a box with relatively shallow sides or ribs (as in the guitar or violin). When played with a bow the waist of the instrument is frequently constricted.

2. THE LYRE. The yoke, the characteristic feature of the **lyre,** consists of two arms rising from the body, often a tortoise shell or bowl, and connected by a cross piece. This instrument had already appeared in the Sumerian cultures. The Greeks employed it for less formal occasions than the ***kithara.*** The

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

strings pass over the soundboard and are fastened and adjusted at the cross bar.

The **kithara** was larger and more sturdily built than the lyre. The two arms like the body and sound board were of wood sturdily joined together and sometimes elaborately adorned. These instruments not only dominated classical antiquity but still survive in the form of the **Nubian lyre.** The lyre persisted in Europe during the early Middle Ages but eventually underwent a change of form. The arms and cross bar disappear as separate features since the instrument is now shaped from one block of wood. Pegs appear as tuning devices. This instrument was also played with a bow and was the ancestor of the **bowed harp** and the Welsh **crwth.**

3. THE HARP. The strings of the **harp** instead of running parallel to the soundboard extend from the soundboard to the tuning pegs set in the neck. The frame of the harp may be curved at the top or the body may meet the neck to which the strings are attached at an angle. The front pillar completing the frame was evidently added to resist the increasing pull of the strings.

In Egyptian culture the harp was the most important instrument. The typical form was curved and was played upright with the body towards the player though other types existed. These instruments were sometimes of great size as is evidenced by the pair of great harps taller than a man depicted on the walls of the tomb of Rameses III (1200 B.C.).

The **minstrel's harp,** esp. famous in Ireland and Scotland during the Middle Ages and later, was wire strung. The strings were plucked with the finger nails and tuned by a key which fitted over the ends of the tuning pegs.

In **Tyrolian harps** of the later 17th cent. iron hooks were employed which could be turned to stop a string, thus raising the pitch by half a tone. This was obviously unsuited to modern music in which chromatic alterations were frequent. The next step was to operate the hooks by a foot pedal. Finally in the **double action harp** of Sébastian Érard the pitch of the strings is controlled by seven pedals (each controlling a note of the diatonic scale and its octave duplications). The pedals actuate rotating discs with projecting studs which raise the strings affected a semitone with the pedal in the middle position, a tone in the low position.

4. THE PSALTERY. In China the classic instrument was a psaltery which was made in several types, each with its distinctive name but always consisting of a number of strings stretched lengthwise over a laterally arched soundboard. The ***ch'in*** was fretted, the ***shê*** possessed a series of open strings. The ***koto*** in its various forms is a similar Japanese instrument.

The ***vīnā*** was the classic instrument in Indian. Here we find a stick or cylinder as a body strung with a variable number of wire strings. Attached gourds serve as resonators. The frets, which are unusually tall and heavy, are movable, so as to adapt the instrument to the complex Indian scale system.

Finally, the psaltery type appears once more in the Arabian ***qānūn,*** a table psaltery in the form of a trapezoid. The strings were plucked with two plectra. In the ***dulcimer*** (Persian ***santir***) on the other hand the strings were struck with two hammers thus employing the basic idea of the piano.

It was apparently the **monochord,** however, which was the most direct prototype of the keyboard instruments. Originally a single string stretched over a sound board, and furnished with a movable bridge, it was a scientific instrument used to measure intervals. The strings were multiplied in later examples. The **clavichord** seems to have evolved from this monochord with several strings. The keyboard operated what were in effect mechanically actuated bridges. As the finger depressed the key, a brass rod flattened at the end (tangent) rose and struck the string above, setting it in vibration and determining its sounding length as a bridge at the same time. Interwoven strips of felt acted as dampers and prevented the other segment of the string from vibrating. Early clavichords had more than one key and tangent to a string. Later instruments in which each string was sounded by one key only were called "**bundfrei**" in Germany.

In the **harpsichord** and in various forms related to it, the **spinet,** the **virginals,** etc., we again have a series of wire strings stretched over a sound board. Here, however, the strings are plucked by a key actuated jack, which is a plucking mechanism which functions as the jack ascends. The plectrum is mounted on a pivoted slip of wood, however, so that the jack drops quietly back in place ready for use again. The **eschequier** of the 14th cent. may have been a predecessor of the harpsichord.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

The **piano** was a keyed dulcimer. (The early **dulce melos** seems to have had a striking mechanism operated by a keyboard but it does not appear to be closely related to the piano action). Cristofori is generally believed to have made the first piano (oldest surviving example dated 1720). The earliest pianos were without dampers and many had no **escapement**, the device which allows the hammer to drop back immediately though the finger remains on the key, though Cristofori did design an escapement. The gradual development of the modern piano involved an extension of the keyboard, heavier strings, and eventually, as a consequence, the cast iron frame to support the greater tension of the strings. Finally, the invention of the overstrung scale with the treble strings below and diagonally across the bass strings was the last great change in piano construction. Mass production has played a critical role in producing great numbers of these complicated mechanisms, the most important musical instruments in America and Europe. The influence of the small city apartment is shown in the recent vogue for the diminutive spinet model.

6. THE LUTE. It is convenient to divide our discussion of instruments of the **lute group** into the form with a long neck and the form in which the neck is a mere narrowing of the body of the instrument. The prototype of the first class is a stick inserted into a small resonating body such as a tortoise shell or coconut. The Egyptian lute was of this type. The more recent examples are scattered and form less of a series than do those of the other type, the **short lute.** There is, e.g., the lute of the Utrecht Psalter (c. 832 A.D.), the neck provided with six frets and furnished with a circular peg box, the pegs inserted from the rear. Several Oriental instruments are also of this type, the familiar Japanese **shamisen** (Chinese ***san hsien***), the many variants of the Indian ***sitar*** with its wide neck, and the ***tanbūr*** of the Near East. A variant of this type which existed in Italy during the 17th cent. was the ***colascione.***

The **short lute** appears in very ancient times and was at first made of a single block of wood. The top was flat, the back convex, and the body tapered to the short neck. In early examples there was a string to each note. (This form appears in Persia in the 8th cent. B.C., then reappears in the Indian Gandhara reliefs). In China a somewhat similar form was the ***p'i p'a*** and a closely related Japanese form the ***biwa.*** Notable ancient examples from the year 749 A.D. are preserved in the Japanese Imperial Treasury at Nara.

The type may also be pointed out in the Near East. It had reached Italy in the 10th cent. and appears in modified form in a German psalter with a box-like body and a peg box with pegs inserted from the rear. The modern pear-shaped body appears in Spain associated with a peg box which is abruptly bent back.

We return to the Near East which possessed a lute of classic form. The neck was short but clearly differentiated, the peg box sharply bent back, the pear-shaped body built up of thin staves. The strings are in pairs, save the highest which is single. The eastern ***'ud*** is played with a plectrum. With little change save the addition of gut frets it became the European lute. Only with the demands for greater sonority was the neck extended to sustain additional bass strings as in the **theorbo** and **archlute.**

The **bow** apparently originated in Central Asia and was applied to instruments of the psaltery group (the ***ya chêng*** and ***ch'in*** of N. China) as well as to the characteristic Chinese fiddle with its drum-like soundbox (often a section of a large bamboo) covered in front with lizard or snake skin. The bow hair in these instruments passes between the strings (which are usually two in number). This fiddle and its variants have remained popular in China to the present day. The Mohammedan culture utilized a somewhat similar instrument with the handle piercing the body (which is often a coconut) extending below and terminating with a sharp point. The truly bizarre Indian instruments the ***sarinda*** and ***sarangi*** are hollowed out of a block of wood; the top is of skin. The ***sarangi*** is also provided with a second set of metal strings which vibrate in sympathy with the upper set of bowed strings, a trait which recurs in certain European instruments. The ***rabâb*** on the other hand which had been treated as a bowed instrument since 1000 A.D. survived in its simple form. The sound box was of skin and the sides were somewhat pinched to give the bow freer play. The peg box is short and sharply bent back. It became the **rebec** of Europe with curved peg box, wood (or wood and metal) sound board, and with the top at two different levels the higher serving also as a fingerboard. This instrument absorbed traits from the violin in the 17th cent. and became the dancing master's ***pocket fiddle,*** the ***pochette.***

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

The other line of development towards European bowed instruments must begin with the strange fiddles of great size which are depicted in Spanish manuscripts of the 10th and 11th cents. These instruments seem to have been similar to the smaller ***panduri*** of the Caucasus. In the latter instrument the peg box has the shape of a leaf with frontal pegs, straight sides, which converge to the neck. The more important ancestor of the later violin however was the **lyra** with its shallow pear-shaped body with convex back, disc-shaped peg box, and three pegs in the rear. The middle string was a drone, the outer played in harmonics by touching them with the nails. Appearing in Europe perhaps in the 9th cent. it became the fiddle of the Middle Ages. The strings were usually four in number. The fiddle (***vièle***) of the Middle Ages assumed a confusing variety of forms. It was only the systematic spirit of the Renaissance that finally brought order into this diversity. One important trait which appeared was the construction of the body of the instrument as a box with top, bottom and sides or ribs. This characteristic also appears in several Eastern instruments the Chinese ***yüeh ch'in*** and the Japanese ***gekkin.***

In addition to the **rebec** which continued to flourish, the ***viola da gamba*** and the ***viola da braccio*** appeared during the Renaissance. The former group had the form of the modern double bass, flat back, sloping shoulders (lateral tuning pegs) and six (or seven) strings tuned in fourths with a third between the third and fourth strings. The **viol family** consisted of treble, alto, tenor, and bass and added a high treble and a double bass on occasion. The **bass** became the favorite solo instrument. A small bass employing pizzicato effects and using special tunings which facilitated chord playing was the **lyra viol.** All the viols were played between the knees, as the term *viola da gamba* implies (leg viols). The *viola da braccio* was played on the arm as was the early violin. The *viola da braccio* was shallow in the ribs, had a convex back, round shoulders and employed heavier strings than the *viola da gamba.* The ***lyra da braccio*** was a curious instrument with pegs inserted in the flat peg board from the rear, body similar to the viola da braccia and with two drones as well as a variable number of bowed strings. The top of the bridge was flat, necessitating a chordal style of playing. The ***lyra da gamba*** was a bass instrument along the same general lines. Finally we must note the late appearance of bowed instruments with sympathetic strings: the ***viola d'amore*** and the lower pitched **baryton.**

The **violin** differed from the viol with its shallower ribs, rounded rather than sloping shoulders, arched back, narrow fingerboard, and four strings tuned in fifths (g $d^1$ $a^1$ $e^2$). The tone was more brilliant than that of the quiet viol. The classic form of the violin is indelibly associated with the name of Antonio Stradivarius (c. 1640-1737), though known violin makers date back to the middle of the 16th cent. The violin family consisted of the **treble violin,** the **alto** or **viola,** the now obsolete **tenor** and the **violincello.** A high treble violin was employed by Bach and others. The **double bass** with four strings (formerly five or three) has remained more viol-like than the other members of the group. The early **organistrum** (later ***vièle à roue*** or ***hurdy gurdy***) was a stringed instrument in which the strings were sounded by a rosined wheel revolved by a crank. The strings were mechanically stopped by turning or pushing a rod against the string.

The **cittern,** wire strung with fretted neck, flat back and top was played with a plectrum. The **English guitar** was the name of a popular 18th cent. cittern. Similar to the cittern but lower in pitch are the wire-strung **pandora** and **orpheoreon.** The **mandolin** of the present day has doubled strings tuned in fifths like the violin. The body has the typical lute shape although a model with flat top and back is also manufactured. It is a purely melodic instrument and sustains its tones by a continuous vibrato of the pick or plectrum. The **guitar** was a more facile successor to the lute which still remains the basic instrument for the Spanish and Latin American cultures. The **banjo** is essentially a shallow single headed drum provided with a neck and a fretted fingerboard. The older American form was associated with the minstrel show. The **tenor banjo** is smaller, is tuned like the viola, and functions chiefly as a background instrument in dance orchestras.

VII. *Electro-musical instruments.* Electrical instruments are undoubtedly in a preliminary stage of development. Electricity may serve simply as a mechanical aid as in the electric action of the modern organ. It may amplify the tone of an instrument by means similar to those employed in stepping up

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

radio signals. The player of an **electric guitar** plays like any other guitarist but he can increase the volume of tone produced at will. The **theremin** depends on varying the capacity of an oscillating circuit by introducing the hand of the player into the circuit. The **Hammond organ** and other similar instruments employ oscillating circuits of fixed pitch and is controlled externally by manual and pedal boards is a fashion similar to a pipe organ. **musical mentality.** See PSYCHOLOGY OF ART.

MUSICAL PERFORMANCE, MAIN TRENDS IN. *Ecclesiastical spirit.* MUSICA ANCILLA RELIGIONIS: The medieval spirit recognized and controlled the arts as well as philosophy as humble handmaids of religion. After the 16th cent. had rediscovered the human being, Humanism encouraged the growing individualism in musical creation and expression. Thus modern interpretation originated in the fresh air of artistic rejuvenation amid the violent clash between the revolutionary tenets of the Renaissance and the ecclesiastical ideals of tradition.

The name emerging as the noble symbol of ecclesiastical tradition is that of Palestrina—not only the superb composer of almost one thousand works for the sacred service but also their unmatched interpreter. Palestrina's Masses achieved the ultimate objective of ecclesiastical rendition: universality of expression in concordance with the Gregorian chant. Such interpretation, eliminating the individual aspect, was all-embracing in its true sense of the word. Although more than four centuries have elapsed since the birth of Palestrina, his performances have remained the permanent model in liturgy. This fact is clearly demonstrated in the *Motu proprio* given at the Vatican in 1903, when Pius X joined the procession of Popes representing the historic reforms of church music. The *Motu proprio,* written at the threshold of the 20th cent., once more conjured up, in all its ramifications, the performances of Palestrina. Just as this greatest *maestro di cappella* was himself a traditionalist, so the conservation of his interpretative style has unalterably remained the safeguard of the ecclesiastical spirit throughout the ages.

*Renaissance.* 1600, the turning point of the first century in modern times, was marked by a great spectacle. Spellbound with the trends of the Renaissance (the earlier phenomena of which had occurred long before), literati invented the opera. What proved to be of lasting importance in the performance of music was, paradoxically, but the art product of theoretical speculation in a circle of Florentine philosophers, artists and dilletante aristocrats. Inspired by their erudite discussion, composers turned away from the complicated tone rows of the Middle Ages, seeking to restore the classical Greek drama. From the pursuit of such old ideals originated the discovery of new ones. Guided by the humanistic respect for the word and its sense aspects, musical interpretation conquered hitherto unknown regions of emotional expression. Mere vocal display was demoted to secondary consideration. Especially the tone language of the *Nuove Musiche* (the New Music), was to be rendered on the basis of a broad subjectivity, the text poetically leading the musical performer's imagination.

In the newly inaugurated opera the modern orchestra made its debut. Re-organized from medieval beginnings, the theatre band, kaleidoscopic in its variety, accompanied the operatic scenes with those instruments that suited best the changing dramatic situations. The first genius of the opera, Monteverdi, painted as a truly Venetian artist his tone pictures in transparent hues like Titian or Tintoretto. The growing emphasis on instruments was eventually felt in the realm of purely vocal rendition. Particularly, the so-called execution *a cappella* (chorus singing without accompaniment) yielded to hybrid forms of performances, admitting here the organ, there mixed instruments to accompany the choir. Gradually, that idealistic conception of former times, which had ranked

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

*un concerto de voci* (interpretation through the human voice alone) higher than any combination of vocal and instrumental forces, waned. Instead, increasing interaction of vocal and instrumental styles came to the fore.

Everywhere the vocal performance exercised its influence on instrumental rendition. Frescobaldi, probably the greatest organ master of all times, attracted thousands of listeners to St. Peter's in Rome. Here they heard a magic organ playing: fantasies and toccatas rendered like the vocal madrigals, free in style and tempo, expressive as the *belcanto* voice itself. In Cremona, generations of craftsmen, the families of Amati, Guarneri and Stradivarius transformed their small town into the unchallenged metropolis of violin building. Wooden bodies of deepened tonal expression and widened range were constructed, instruments which spoke and sang, laughed and cried like human beings. For centuries to follow this new type of violin held the lead in the orchestral ensemble. This ensemble had its face changed when Lully replaced the variegated set-up of the Venetian with baroque simplicity—just as the multicolored palette of Titian was followed by Rembrandt's ingenious simplicity of contrasting light and shades. Lully's creation of what since has been recognized as the French music style made the score script more specific, i.e., he invested the script with more definite orders for the performers. Previous generalizations such as *tutti instrumenti* yielded to individually prescribed instructions for each instrument and its player. The whole orchestra at the royal court opera of Louis XIV was located between the parquet and the stage, the place it now holds in the opera houses of the world.

*Baroque.* A freak of nature selected the year 1685 for the birth of Bach, Handel and Scarlatti, and so marked the turning point of a new era, usually referred to as *baroque.* However, the general aesthetic meaning of the term *baroque* has caused more confusion than enlightenment in so far as the interpretation of works in this period is concerned. It has been the fate of the word baroque to lend itself to frequently changing meanings. From the original Portuguese *barrocco* (the fisherman's word for a small irregular pearl) through the characterization of features in the arts that tend to irregularity, to the final conception suggesting vastness of proportion and splendor of colors, the road is long and winding. And so are the ways of performing those masterpieces in music which today are labeled as baroque in analogy to ampleness in architecture and stateliness in sculpture and painting. Modern performances of Bach and Handel, the gigantic representatives of the musical baroque, are based on certain aesthetic traditions and on a partly hypothetical musical practice.

When Bach died in 1750 there was little realization of the spiritual wealth the Leipzig cantor at St. Thomas had bestowed on mankind. His works were hardly known until Mendelssohn reawakened the *St. Matthew Passion* in 1829. Thus there is a long void in which no real tradition in the performance of the great Bach scores could have been established and the so-called authentic German Bach tradition is in reality something hypothetical. The English Handel tradition developed into a performing routine on the grand scale. Thus, the famous *Messiah* rendition in Westminster Abbey (1784) exemplifies in its use of masses of participants, in its stolidity and rigidity, typical performing habits of the late baroque. Bach himself limited his performing apparatus to one of striking economy. Declaring his needs for the due rendering of church music, he asked the city council of Leipzig for a minimum of 18 orchestra players and three singers for each part. In Bach's own conception vocal and instrumental forces appear equal, very much in contrast to the modern Bach practice, where the size of the chorus often doubles or triples that of the accompanying orchestra. Both Bach and Handel are the favorite subjects of modern orchestra arrangements, of often rather forceful attempts to translate baroque sound ideals into the past—romantic accoustical conceptions of our time. Such endeavors lead to coloristic misrepresentations of the genuine baroque 18th cent. style, its vast horizontal planes and its organ-like orchestration.

*Rococo, Dance types.* The graceful rococo era brightened everything up. Its ornamental world cleared the severe counterpuntal baroque execution into a playfulness of melodic charm and serene elegancy. A lacework of grace notes, marked in notation by a clever system of musical stenography, served simultaneously to prolong the short-lived tone of keyboard instruments like the harpsichord. Thus, the seemingly only decorative performance of ornaments proved to be functional and progressed soon into the expressiveness of Romanticism.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

In the periods of baroque and rococo, the performance of dance types underwent its most radical changes. The fact is due to the style transformation of courtly and popular models at their integration and absorption through the instrumental suite and orchestral symphony. Such changing performance of one and the same form type with the same unaltered name is but another instance demonstrating that the idea of musical forms is not absolute. Interpretation of any musical type is relative to time, place and function (purpose) of the respective rendition, interdependent on its style. What has been called a madrigal or minuet proves to be unlike in idea and execution with the shift of circumstances. The dance type sarabande, characterized as austere and of stately restraint in keeping with its slow and serious baroque performance was danced in the 16th cent. in Spain in a manner which made the law makers intercede; for dancing the Spanish sarabande, girls were exiled from the kingdom and men were sent to the galleys for six years. Analogously, the performance of other dances displays so drastic a metamorphosis that their story reads like an Ovidian tale.

*Doctrine of Affections, Rationalism, Emotionalism.* Rationalism, the back to nature watchword of the time, and its sweeping emotionalism were bound to leave their traces on the contemporary performance of music. The imprint of these ideologies is clearly marked in 18th cent. theories of interpretation. Concurring upon the fundamental approach to reading music, the theories center around the so-called *Affekten-Lehre,* the Doctrine of Affections or emotions (the German ***affect*** being synonymous with the English emotion). This *Affekten Lehre* is a practical aestheticism, a thorough system of performing practice. We understand best its implications by quoting some of its leading exponents: "The true aim of music is to stir emotions" states Mattheson, and Heinrichen's formulation holds the same, "The purpose of the performance is to move the affections". Bach's son Carl Philip Emanuel explains that "interpretation must realize the musical thought in accordance with its affections". Unequivocally Quantz demands that "the performer must recognize always all emotions embodied in the score". Without exception the theorists (most of them expert composers and performers) demand a conscientious scrutiny of the score's emotional content and its suitable application in the rendition.

The source of all musical truth is to be discovered by natural reason. A rational approach applies its rules and regulations according to different types of performance—in the church, the theatre, the home, the open air performance. For his discernment of the score's emotional content the performer depends also on technical features such as the tempo, the key, the phrasing. A staccato in an opera, symbolizing a slave's heart beat, was to be executed irregularly. Yet another staccato, illustrating the pulsations of sinners at the death of Christ must be played in strict time—two different emotions in two different style categories!

*Classicism.* With the great masters of the Vienna Classical School-Hydn, Mozart, Beethoven and Schubert—the score script becomes increasingly binding. The score text and its execution enter a new state of interdependence. As the classical score tends to exclude licenses on the part of its interpreter, it shows more frequently and in more details what the composer wanted. The *basso continuo* or figured bass, that inevitable characteristic of the previous practice, where the keyboard player improvised his part over a fixed bass line with indications for the harmony to be chosen, gradually vanishes. The classical close bond between the composer and his interpreter is tightened by a specific group of signs in the score script. These symbols of notation consist in the marks of agogics, dynamic and phrasing (the disciplines of tempo, tone volume and and musical punctuation respectively). Their employment is not new in the classical score. From the last part of the 18th cent., however, these marks are used profusely and have developed in modern music into minute directions concerning the composers' wishes, into detailed verbal information, into almost a musical scenario.

Summarizing, the classical attitude in the interpretative problem may be expressed in a dual formula: (1) the binding script and (2) the disappearance of improvisation and its chief device, the figured bass.

*Romanticism.* History has long linked the inception of romanticism with the end of the classical period. Yet, romanticism is an eternal factor in the performance of music. All epochs created romantic works and no period has any special claim on romantic interpretation. If romanticism stands for a more humanized way of playing music—with the emphasis on the subjective, the emotional, the phantastic and the virtuoso element—then

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

it cannot be confined to the 19th cent. styles of composition and interpretation. The performing style of the *Ars Nova,* the stressing of the poet's word in the Renaissance, as well as the free "fantasies" of the baroque must be considered just as romantic in the sense of the definition given above. Even the classicists played quite romantically under certain artistic conditions. In short, before its gradual development into the most significant style-building principle of the post-classical era, romanticism was operative as a latent force in the musical interpretation of former periods.

In the middle of the 18th cent., however, a new style emerged, a style of a highly emotional nature which embodied the 17th cent. tendency toward a humanized performance and the 18th cent.'s interest in timbre. Interpretation of this new style employed all possible timbres, not in the service of polyphonic contrast and distinctness, but for the sake of emotional expressiveness. A new sensibility, a tender *cantabile* appeared, first with the scores of Philip Emanuel Bach, later with those of Mozart. Yet still another generation was to pass before these characteristics were fully absorbed by the forthcoming style of interpretation which dominated musical rendition throughout the entire 19th cent. The new trend romanticized not only the music of its own time but that of the past as well—the performance of the classicists became romanticized; the general style of interpretation had changed once more. Not the classical counterbalance of content and form, but the performer's subjective experience gradually rises as the driving force of the personalized 19th cent. interpretation. The interpreter no longer merely performs; he "reproduces" the art work. This word implies that the specific process of re-creation is being considered. The employment of the interpreter's mental and emotional qualities are claimed as being imperative in the rendition of a music which itself is but the manifestation of the most subjective experiences in life; a music wherein the composer has sublimated his world of dreams and visions. Even if such sublimation-music could convey a hidden meaning solely throughout the note-script, it would still be impossible for the performer to delineate with objective reserve the extravagance, buoyancy and emotionalism of such highly romantic and phantastic works, to use compass and ruler for his orientation in a truly dream world.

The classic score may lend itself to the tracing of its contours, for it is so splendidly adapted to formalistic copying on the part of the performer. But the romantic forms have been relaxed for the sake of new expressive forces. With romantic music, the aim of the performer has ceased to be abstract, as in a fugue or symmetrical sonata form. The romantic performance becomes more and more an appeal to the listener's imagination, to his subconsciousness—is more exciting than the plea of the baroque interpreter for conscious intellectual understanding. In striking contrast to the interpretive attitude of romantic freedom, there also prevails the heterogeneous thought: strict allegiance to the score. Despite the new expressive enrichment of the romantic technique, the tendency to preserve formalistic ground within the performance of music became manifest. Even in the theatre, with the gradual separation of the music drama from the opera, there reappear reformative approaches in the production of dramatic scores, leading to perfect coordination of the scene and the music. New designs for rehearsing, utmost conscientiousness in the preparation (of decors, the singers' acting, the dancing, and the orchestral part), led to renunciation of even the smallest licenses indulged in by vocal luminaries. These are the highroads to the unified art work of the future.

This trend culminated in Richard Wagner's *Gesamtkunstwerk* (see universal artwork) and its realization through the idea of *Festspiel* in Bayreuth. Historically, the reforms of Lully, Gluck, Weber and others are consummated in this 19th cent. craving for dramatic truth in opera performance. If Wagner's interpretative theory (as formulated in several splendid essays) appears as the quintessence of German Romanticism, so Hector Berlioz epitomizes the romantic ideals of French interpretation. Not only his dream of power and a colossal set up for performing masses but also his defense of the pure spirit of rendition gained lasting significance. He considered corrections of masterworks "the most enormous of crimes". At the other extreme, the corrective attitude of the interpreter towards the score may involve a multitude of deviations from the original when, e.g., for practical or aesthetic reasons, he resorts to the rendition of arrangements. As the title arrangement, revision, transcription, etc., imply, these versions differ from the prototype of the score and may, in spirit and expression, even lead to the exact opposite of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

what the composer wanted. Affinity between corrective approach and the virtuoso approach to performance, however, is to be found in the fact that frequently the exponents of either trend are identical. Thus the names of Liszt and Paganini live on as symbols of the triumph of the human mind and will-power over the hand and as arrangers of striking originality. Again, their style stresses the histrionic element in performing music; they accommodate their program, behavior and appearance to the desire for the spectacular of the spoiled *haute volée* in the European capitals of their time.

*The Absolute Ideal.* The train of thought in 19th cent. interpretation which proved most prophetic for developments in our own time emanated from the aesthetics of the greatest man in German philosophy—Imanuel Kant. It was Kant's *Critique of Judgment* on which Eduard Hanslick based his famous treatise, *The Beautiful in Music* (*1854*). This revisal of musical aesthetics stood and still stands as the manifesto of objective interpretation—as the defense of the absolute subject matter in music. Inspired by Kant in principle and formulation, Hanslick shows that an investigation of music must, above all, consider the art *object* and not the perceiving *subject*. Just as in the other arts, so in music, too, the objective mode of procedure must be adopted. Consequently, the interpreter's task is to realize music clearly as a self-sufficient form. This form—as proven in the *Critique of Judgment*—must always be in complete harmony with its content. Like the song of birds, music has no subject matter, it is the art of the beautiful play of sensations. With the existence of any extra-musical subject in the score wholly denied, the interpreter's question, "What is to be expressed in my performance with the material at hand"? is answered categorically: "Musical ideas, nothing else!" Thus, lacking extraneous material as a premise of interpretation, the executant is obliged to think exclusively in terms of sound—as did the composer before him. Music is to be played, but is not to be played with. Interpretation deals with the *absolute* intrinsic beauty of tonal combinations as an end in itself. An aestheticism based on Kant's absolute ideas was bound to result in a conflict with Wagner's interpretative theories, esp. in the realm of absolute music, and to foster in the world of Brahms the inwardness and formal tendencies to be found in this composer's chamber music style.

*New Gateways.* Revolutionary inventions of electro-mechanical means have opened new gateways for the performance of old music as well as of music still to be written. Today, investigation of the mutual relationship between the artistic and technical features, must naturally consider all the seemingly extraneous factors which surround the electrical rendition. Such a factor is the time element, imposing specific conditions on both the musical and the technical executants. Again, the very existence of this performing team (the sound engineer collaborating with the performing musician) indicates the obvious departure from the past practice. Other problems, necessitating readjustments of the past ways of performance are entailed in electrical transmission. Also, a series of psychological ramifications cannot be neglected. The performer before the microphone is not stimulated by a visible audience, nor can the listener of a recorded or broadcasted rendition be influenced beyond aural sensation. Social stimulation, however, has been claimed an essential factor of performance by authorities of the stature of Schumann. The stylistic approach of the romanticists counted on the combined aural and visual reactions of their audiences. In contrast, the modern invisibility of performers reemphasizes the interpretive condition of classical formal lucidity instead of improvisatory display, the qualities of clarity and concise tonal balance rather than romantic dynamism.

Whatever can be said of the performer's or his audience's invisibility as a major factor determining the style of interpretation will, of course, be outmoded the moment television is made generally available to the public. To what degree the visual will be emphasized remains to be seen in the literal sense. If the accent is again, as in certain 19th cent. trends, on the performer's antics, then the streamlined magic box of the future will take the music lover back to the performing manner of a past long considered dead. Like all technical progress of mankind, its advancements may lend themselves to either course: to the conquest of the truly new, or to reactionary, perverse and frequently destructive employment. At any rate, an eternal law seems to emerge from the retrospective sketch of performing trends: the constant spiraling of heterogenous styles throughout the ages of musical history. (The above is based on the author's book, *The*

**music appreciation** (in the U. S. A.). The term *music appreciation,* which came into use early in the 20th cent. has found its way into our educational institutions as a course of study offered in most colleges and public and private schools. It may also be considered as expressing the state of music reception in communities and, according to the dictionary definition, it should express true or adequate estimation or recognition of the music of various ages and stages. To *appreciate* is "to be keenly sensible of or sensitive to",—therefore, courses in music appreciation are offered to cultivate and develop a love for and understanding of music as listener, performer and creator. *Appreciation* of music implies enthusiasm in its pursuit either active or passively, growth in understanding of its techniques and skills, and of its historical and aesthetic backgrounds.

Whether in a study course or as a measure of advancement of culture in this country, true appreciation of music should include not only a love for it, but also a recognition of styles, formal structure, instrumental color, harmonic and melodic structure, the dynamics necessary in interpretation, and a knowledge of the standards of various eras such as Classical, Romantic, Impressionistic, etc., and of historical and biographical material.

Familiarity is the keynote of music appreciation. We are living in an age when music is much more available to the masses than it was even in the last generation. Therefore, through radio, phonograph, the movies, free band concerts, symphony concerts, children's symphony concerts, community choruses, singing societies, recitals, school orchestras, bands, and choruses, music is literally within reach of everyone. The phonograph, by means of which the same composition can be heard innumerable times, is a powerful factor in increasing music appreciation. Another important point in the development of music appreciation is the widespread growth of music organizations in the schools, giving thousands of young people opportunity to participate in the making of music, thus arousing an interest in and, frequently, increasing their love for music. Through school bands, orchestras, and choruses, larger audiences are developed for the concert halls throughout the country, in this way enlarging the scope of music appreciation. Today, the radio devotes more time to art music than it did formerly. The extent of this manner of disseminating musical culture or appreciation can hardly be measured. Beethoven symphonies, Mozart operas, Schubert songs, Bach fugues, works by contemporaries, penetrate into lumber camps, mining towns, lonely ranches, forestry look-outs, and into the home of factory workers and of shut-ins.

A love of music may be awakened through listening to popular and folk music, too. Many who have not been privileged to hear any music at all have frequently been led to listen to so-called classical music through being attracted by popular music and jazz heard over the air. While this method of leading listeners to the best through popular music and even popular classics is perfectly possible, musicians and teachers as a rule object to the idea of "swinging" the classics. At best it is not a legitimate treatment of music, and those who claim that people are drawn to listening to standard works by hearing them in swing version first, may be rationalizing or seeking to condone such maltreatment of music. Swing versions of Debussy, Mozart, Tchaikowsky, etc., must not be regarded as part of music appreciation.

The many music courses for the layman which have come into existence in the last few years may be cited as a sign of the growth of music appreciation.

While it is beyond the scope of this article to offer statistics, in a *Survey of College Entrance Credits and College Courses in Music,* published by the National Bureau for the Advancement of Music, New York, the statement is made that "over three-fourths of the 594 institutions (colleges) investigated offer some instruction in music. . . ." Most of these colleges offer courses which partake of the nature of music appreciation.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

A decade ago, Augustus D. Zanzig made a study of music conditions in the United States. His book, *Music in American Life,* reveals the musical activities of schools, playgrounds, playgrounds, settlements, homes, churches, industries, and museums. It shows the state of amateur music in 1932 and offers a working guide toward greater musical achievement. To encourage the development of musical appreciation through amateur participation is Dr. Zanzig's aim.

A phase of music appreciation which has widespread influence is the *Music Memory Contest,* an idea which originated in 1916 in the home of Mr. C. M. Tremaine, director of the National Bureau for the Advancement of Music. So successful was the experiment of playing music rolls and records for his children to learn to recognize a selected list of pieces, that the game was introduced into the schools of Westfield, N. J., where the Tremaines live. In 1928, more than 1500 school systems carried on Music Memory Contests, run according to given rules and a constitution. The Contest succeeds in its original purpose of cultivating among school children an appreciation of good music.

National Music Week, which is annually proclaimed by the President of the U. S. A., has done much to create a nation-wide interest in music in schools and communities. The number of school orchestras, bands and choral groups participating in National Music Week entertainments is unbelievably large, reaching into five figures.

No stronger proof of the growth of music appreciation in this country is necessary than to call attention to the increase in the number of great symphony orchestras in American cities. New York, Boston, Philadelphia, Chicago, Pittsburgh, Cincinnati, Washington, St. Louis, San Francisco, Los Angeles, Seattle, Baltimore, Cleveland, Minneapolis, Detroit, Kansas City, are a few cities with ranking orchestras and dozens of others are coming into prominence.

The more opportunity the public has to hear opera, the sooner will appreciation of opera increase, and with the development of taste will come the demand for more opera houses throughout the land. —M.B.

**music-culture.** The aim of the liberal arts college is to develop all of our human gifts into free recourse, and through rounded training to cultivate and integrate the whole personality. To receive and store facts is a necessary part of the educational process but to this must be added the power of deducing from experience general and constructive principles. To be valid that experience must emerge from the accumulated riches of the intellect, the emotions and the spirit. Through the ever-increasing emphasis, since the Renaissance, upon analysis and specialization this triad of sources and forces has become disintegrated, losing the revealing and inspiring power they derive from active correlation. The science and art of music has suffered the most of all the seven arts by reason of its separation and academic segregation from life and general learning. But since 1927, with the formation of required and integrated courses in the humanities (architecture, sculpture, painting, poetry and music),—called by the Oriental sage: "The five fingers of God" —music as a vital element in liberal education has come into its own and its intellectual and cultural content and contribution to a general education is increasingly recognized and applied.

When the subject of music-study is mentioned the vast majority of adults or young people think of it as meaning music in one of two dimensions, i.e., applied music (learning to play or sing), or theoretical music (learning to compose and analyze). The history and tone-literature of music—folk and art music—constitutes an intimate record of man's thinking or intellectual self as well as man's feeling or emotional self. The development of races and nations is reflected in historic streams of beauty created by man. Just as in history, literature, and philosophy, so in music, it is our right and privilege to interpret, to apply and to re-live the truths recorded and expressed in its sensitive tone-literature. The tone language and message of music can only become a practical agency for cultural growth in the lives of all students, irrespective of musical tastes and tendencies, when its intellectual demands, its social and spiritual relationships are acknowledged and applied.

The teacher of the music-culture section in the conscientiously integrated humanities trunk course (running through at least two years), should be of necessity broadly equipped. He should be an able performer and a devoted lover of the best in folk and art music. Furthermore, he should be thoroughly versed in general history, literature and philosophy; in other words, a "man of culture", as the Greeks called such a human unit. Without this intellectual background convincing and stimulating integration is im-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

possible, and the claims of music to be the mirror of men's thinking and feeling through the centuries fail to dignify the musical material or to reveal to the student its powers to interpret the society which created it. The teaching of music-history as such in a seriously integrated humanities group-course results in the loss of the high position and potential power of music-culture as an indispensable element in liberal education. Today men and women, musicologists in the best sense of the word, are available in increasing numbers. These scholars not only recognize the place and power of Music [in its three dimensions] in general education, but can constructively apply their knowledge to the interpretation-through-music of life past and present.

Music-culture as an accepted major element in general education opens the door of inspiring opportunity to educators and to the legions of students who are denied the understanding and appreciation of music through their false belief that the gods have not given them adequate tonal gifts and aptitudes. Music-culture integrated with history, literature and the arts is here to stay in the curriculum of the liberal arts college. The fundamental triad of things, thoughts, and emotions is as basic to a rich liberal education as it is to music. The understanding and application of its integrated relationships and creative possibilities truly educates ( leads out) the total personality. Music, creative, applied and cultural, is fast becoming the emotional interpreter and spiritual leader of humanistic education in the liberal arts college. —H.P.E.

**music, definition of** See idiom B(6).

**music drama.** See opera.

**music education.** Music education, from the very nature of music itself, is designed to develop the ability to hear, the ability to understand what is heard and the ability to participate in the aural experience as a medium of expression. It involves the training of creators, performers and, in the present day, audiences.

The education of the professional and avocational musician differs only in the degree of intensity and extensity. Basic training for creators and performers includes (1) the learning of the relatively complex system of notation, consisting of a wide variety of signs and symbols; (2) the learning of terminology; (3) the acquiring of a sense of pitch (except in the cases where the sense of absolute pitch is present); (4) the development of a definite feeling for metric and rhythmic groupings and tempos; (5) the learning of the aural and visual recognition of the components—rhythm, melody and harmony—and of the form and style into which they are cast; (6) a knowledge of the tone quality of the physical media of music, both in solo and ensemble; (7) the technical ability to perform music.

The learning of the notation and terminology is largely incidental and continues over a long period.

Lacking the sense of absolute pitch, a fairly accurate sense of pitch is acquired by constant attention. (In music schools courses in solfeggio or sight singing and dictation emphasize this.) The knowledge of pitch assists in making visual music aural and aural music visual.

To this must be added the developed physical feeling for metronomic divisions (meter), for related tones logically arranged in time relation (rhythm), and for established degrees of movement (tempos); a discriminating recognition of tone quality and a knowledge (first aural, then academic) of melody, counterpoint and harmony and their relation to form and style. The performer is then able to hear the printed page and the composer to write down what he has created.

Technical ability is merely a skill and, while necessary for a high degree of artistic performance and while definitely related to certain phases of music education, will not be taken up here.

The most advanced methods in music education approach the printed page as something to be heard before it is actually performed. As evidence of this mental hearing the student is asked to sing the music to be performed, in the case of melodic lines, and to analyze it harmonically in the case of chordal progressions, the material used being within his aural and mental experience. Having studied the phrases and larger divisions as a whole and having been instructed in the necessary technical skill, the student not only interprets the work of the composer but is able to use the music as a medium of self expression.

Creative music plays an important role in music education, just as original composition does in the study of a language. Students at all stage of advancement, even as beginners, learn to express themselves in music which they have created.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

The history of music is being taught more and more against a background of world history with special attention to the philosophy of its transitions.

Courses for advanced students include the study of music in its cognate fields—acoustics, psychology and aesthetics. —M.E.

**MUSIC HISTORY, PERIODS IN.** Like any other art, or any specialized activity, music may be viewed in two aspects—that of its purpose, and that of its technique. The purpose of music, aside from its sensuous appeal, is to utter (in intelligible and gratifying form) emotional appeal to, or emotional attitude toward, experience. Its technique is the adaptation of its materials (tone and rhythm) to that purpose.

The manipulation of tones and rhythms is itself a highly specialized activity, which often appears to the artist as the essential and even the only proper object of his effort. Those periods in which this view has been held are generally regarded in retrospect as periods of decadence. Those, on the other hand, in which extra-musical interest has generated new musical purposes are regarded as periods of growth. Since music thus derives in part from experience, its evolution pursues the general curve of human experience; and the great historic divisions of musical activity thus correspond to the great divisions of the history of mankind.

These divisions, however, are conveniences for thought, rather than temporal realities. The stream of musical thought, like the stream of human endeavor, is continuous; the forces which deflect the stream are often all but imperceptible at the instant of impact; and it is thus necessary to look backward as well as forward for any certainty of critical orientation at any given moment. The following is an attempt (utilizing the convenient but deceptive method of periodization) to indicate the course of the stream of musical thought from the earliest times until our own day. Other systems of music than our own, and systems so remote that their technique is unknown, obviously lie outside the scope of this survey. The aspects of purpose and technique have been differentiated up to the modern period, where such indication would be cumbrous and probably superfluous.

I. *The Ancient Period.* THE MUSIC OF ANCIENT GREECE. The purpose of Greek music was the enrichment of poetic ideas and poetic contours through the systematic organization of elements of pitch (in verbal accent) and of rhythm (in quantitative verse-structure) already existent in Greek speech. Because of the close association with language, ethical implications were embraced which are no longer perceived in modern music.

Out of the tetrachord (e.g., E D C B) was developed, by juxtaposition, our present diatonic scale. Segments of this scale (modes) were the progenitors of the Gregorian modes, and of our major and minor tonalities. Harmony, not practiced, was faintly imagined. Instrumental music, though highly perfected, remained subordinate to vocal (See Greek Music, ancient).

II. *The Medieval Period (150-1300 A.D.).* (a) MONODY (non-harmonic music), c. 150-900. The first purpose of Christian music was to find expression for the ideal of a universal brotherhood in a universally practicable form, the Hymn. Later, for the enrichment of an elaborated ritual, the stylized Gregorian chant, derived from Greek and other "classic" models, largely supersedes the "popular" hymn.

The rhythm of the hymn derived from its accentual verse; its melody, probably from popular song. The chant (set to prose texts) derived from Greek and Hebrew sources; was governed by modal law; was practicable only by the trained singers. Codified under Gregory the Great (d. 604), the chant assumed a form which has remained substantially unchanged to this day. Further musical progress is unrecorded until the 9th cent.

(b) THE BEGINNINGS OF HARMONY: ORGANUM (900-1100). The chant is reduplicated at non-unisonous intervals (perfect 5th and 4th) as well as at unisonous (8ve). Through effort to avoid imperfect 5th and 4th, the 3rd occurs, and is recognized as imperfect concord. Contrary and oblique, as well as parallel motion between the voices, produce combinations of two or more *different* melodies, thus establishing the fact of *harmony*—probably the most remarkable artistic invention in recorded history. (Popular melody, still monodic, is continuous, but unrecorded, in this period.) Notation of pitch (but not of rhythm) becomes exact.

(c) DISCANT (RHYTHMICALLY MEASURED MUSIC), 1100-1300. Secular life is reflected in the poetry and song of troubadours, trouvères and the minnesinger. Popular melody is assimilated into learned music (motets).

Regular rhythm (essential to practice of harmony) is established on a basis of poetic meter (six rhythmic modes). Relation of discord to concord begins to be regulated; rhyth-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

mic periods are defined by pauses and cadences; musical form begins to show independence of poetic structure, but is hampered by a narrow rhythmic scheme (triple time, exclusively), and by failure to yield melodic interest to the advantage of harmony and general design. Notation becomes exact for triple time.

*III. The Renaissance* (1300-1600). (a) THE PRE-RENAISSANCE (1300-1400). Service music is greatly enriched (polyphonic settings of the Ordinary of the Mass); secular interests are greatly expanded; instrumental music is admitted into learned forms.

Duple rhythm is recognized, with appropriate notation. The musical sentence acquires a beginning and a middle, as well as an end. Structural devices (imitation, augmentation, diminution) are increasingly cultivated. Musical form becomes independent of poetic meter and verbal sentence. The relation of concord to discord is still indeterminate, and the forms inchoate; but liberation from modal rhythm compels attention to purely musical syntax. Chromatic alteration (*musica ficta*) begins to undermine the church modes, tending toward modern tonality.

(b) THE RENAISSANCE (1400-1500). Principles of composition are broadly determined: discord is "prepared" and "resolved" (Dunstable, d.1453); imitation becomes a principle of design, instead of a mere device (Dufay, d. 1474); "scientific" composition is carried to great heights (Okeghem, d. 1496); and the composition acquires a beginning, a middle and an end through the mastery of coherent harmonic progression underlying the whole fabric of interwoven melody (Josquin des Drés, d. 1521). Instrumental music begins to diverge from vocal (Paumann, d. 1437), and to express popular sentiment in dances and other forms. Patronage makes possible the musical career.

(c) RENAISSANCE AND REFORMATION (1500-1600). The process of polyphony is perfected, as applied to Catholic ideals (Palestrina, d. 1594); is expanded to reflect secular feeling (in the madrigal); and is abandoned to allow melody to predominate over harmony, in experiments leading directly to opera. Protestant doctrine, reasserting the individualism of early Christianity, is expressed in the hymn (chorale), sung as if monodic by the congregation; but harmonized by the choir, and embroidered by the organist, the hymn lays a foundation for a second polyphonic period. Instrumental forms are multiplied and expanded: fugue, fantasia, dance-suite, etc., and instruments are combined with choirs. New alliance is formed between music and poetry, linking music definitely to the humanities.

*IV. The Modern Period* (1600-1900). (a) THE SEVENTEENTH CENTURY—THE MONODIC REVOLUTION. Opera appears (1600), is rapidly stylized (Lulli, d. 1687, and Scarlatti, d. 1725), with recitiative and A-B-A aria as principal forms. It greatly expands the musical public, becoming largely independent of aristocratic patronage, and thus generally affecting taste. Religious music adopts a secular tone, admitting brilliant instrumental accompaniment. Instrumental forms are perfected: concerto, sonata da chiesa, sonata da camera, fugue, etc. Major-minor tonality supersedes the church modes. The problem of equal temperament is solved.

(b) THE EIGHTEENTH CENTURY TO C. 1750. Opera is degraded in taste, perfected in technique of performance (singers the first virtuosi). Harmonic polyphony (as opposed to modal) is perfected (Bach, d. 1750); oratorio supplants opera in England (Händel, d. 1759). All musical forms greatly enriched, with wider expressive range, owing to application of equal temperament. Comedy appears in opera (the *Guerre des Bouffons* a kind of aftermath of the *Guerre des Anciens et des Modernes* in literature).

(c) THE EIGHTEENTH CENTURY, 1750-1800. Opera is "reformed" (Gluck, d. 1787), reflecting the "return to Nature"; but popular taste abandons polyphony for homophony in all forms, due to the influence of opera, the brilliance of aristocratic life, and the inclusion of lower classes in the musical public. Drama is incorporated in instrumental music (perfected sonata or symphonic form—Haydn, d. 1809, Mozart, d. 1791). Classicism declines and is overthrown by the Revolution.

(d) THE NINETEENTH CENTURY TO C. 1850—THE ROMANTIC PERIOD. High individualization in all forms, vocal and instrumental. Rise of the lied (Schubert, d. 1828); vast expansion of the symphony (Beethoven, d. 1827); romantic opera appears (Weber, d. 1826); sentimental opera superseded by "historic" (Meyerbeer, d. 1864). Smaller instrumental forms multiply (Chopin, d. 1849; Schumann, d. 1856) together with the song. Virtuosity, rampant (Paganini, d. 1840; Liszt, d. 1886), increases vastly the musical public, and fosters program-music (Berlioz, d. 1869). Great freedom in the use of modulation and discord.

(e) THE NINETEENTH CENTURY, 1850-1900. Conflict between radicals and conservatives:

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

"expressive" vs. "absolute" music: Wagner (music-drama) and Liszt (symphonic poem) vs. Brahms (symphony). "Intellectual" criticism arises (Hanslick, et al.) in defense of absolutism. Bruckner and Mahler (symphony) and Hugo Wolf (song) continue Wagnerian tradition; Richard Strauss (symphonic poem) initiates new freedom in dissonance. Impressionism (Debussy) offers veiled threat to tonality (whole-tone scale). Reger expands Brahmsian structure on liberal harmonic lines.

*V. The Twentieth Century.* Absolutism becomes radical: polytonality and polyharmony (Milhaud et al.) and atonality (Schönberg) diffuse or obliterate tonality. New musical forms derive from intrinsic characteristics of the material employed, theoretically abandoning all relation either to emotional experience (as in romantic expression of mood or feeling) or to verbal syntax and rhetoric (until now, the implied bases of all musical form-patterns). From c. 1935 opposition to absolutism, although inarticulate critically and without a notable champion creatively, becomes strong. (As in many earlier periods, popular music is both affected by and absorbed into learned forms). —D.N.F.

**musicology** (fm. Fr. *musicologie*). Musicology concerns the discovery and systematization of all knowledge pertaining to music as distinguished from the activities of musical composition and performance. It is the *science* of music as contrasted with the *art* of music, in that it stresses *knowing* rather than *doing.* As knowledge and understanding of music are basic to performance, so musicology underlies the art of music. But dependable knowledge requires careful study and investigation; hence musicology has come more narrowly to mean the field of musical research.

A fundamental characteristic of any science is that it attempts to refine the knowledge of ordinary common sense by applying objective, scientific methods in the investigation of its subject matter. Thus the main function of musicology is the scientific description, analysis, and explanation of music in all its varied complexity. In the orderly performance of this function, musicology incorporates the findings of many auxiliary sciences, such as acoustics, physiology, psychology, aesthetics, education, ethnology, and history as they relate to music.

The fundamental philosophical concepts of *space* and *time* form the main axes in the frame of reference in terms of which musical knowledge and understanding are expressed. Just as the understanding of a musical composition depends upon the perception of the relationships among the constitutive tones in both their simultaneous and successive aspects, so the understanding of music in part or as a whole depends upon the perception of both systematic and historical relationships. Naturally, then, the subject matter of musicology falls into two main divisions: the *systematic* and *historical.*

The main objective of **systematic musicology** is the study of music as it exists in the world today. Musicology investigates music as a physical phenomenon under the heading of *acoustics*; the nature of the responses and activities of the human organism in reaction to the physical sounds of music under the headings of *physiology* and *psychology;* certain problems of musical value under the heading of musical *aesthetics;* the problems of teaching music under the heading of *pedagogy;* folk music and the musical systems of the various peoples of the world under the heading of *comparative musicology;* and finally the tonal-rhythmic structure of music under the heading of *musical theory,* with numerous subdivisions such as *harmony, counterpart, orchestration,* and *musical form.*

Thus based upon the study of actual musical works in the light of findings in all these auxiliary sciences, musical theory, in a comprehensive sense, constitutes the chief purely musical division of systematic musicology.

The main concern of **historical musicology,** on the other hand, is the study of music as it existed in the past for the purpose of understanding or explaining how it came to be what it is today. In the attainment of its aims, historical musicology investigates the principles basic to a comprehensive and valid *philosophy of history;* it seeks to collect, classify, and preserve all pertinent source materials; and, finally, it attempts to express its findings in the manifold types of historical literature.

The systematic and historical orientations of musicology are complementary; they find their common application in innumerable characteristic musicological publications. The scientific study of music in Western civilization extends back at least to Pythagoras, in the 6th cent. B.C.; and from the time of the early Greek and Latin writers on down to the present there has been a steadily increasing volume of musicological literature. The natural seat of musicological investigation and teaching is the university. This fact has long been true in Europe and is rapidly coming to

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

be true in America. The American Musicological Society, founded in 1934, is one of several national and international organizations devoted to the promotion of the scientific study of music. See Glen Haydon, *Introduction to Musicology: A Survey of the Fields, Systematic and Historical, of Musical Knowledge and Research,* 1941; Otto Kinkeldey, "Musicology," *The International Cyclopedia of Music and Musicians,* pp. 1218-1221; Egon Wellesz, "Musicology," *Grove's Dictionary of Music and Musicians,* Suppl. Vol., pp. 455-462. —G.H.

**music, origins of.** The problem of the origin of music can scarcely be taken as a question of absolute beginnings. It is a matter, on the one hand, of discovering the historical evidence of the first known existence of music and, on the other, of studying systematically the conditions basic to the manifestation of music in the experience of the individual and of society. A comparative examination of the historical and systematic evidence affords the natural and logical, if not the only, scientific approach to the solution of a problem, which, like many problems of origins, is not susceptible to a definite answer.

Since the evidence of historical research, leading back several milleniums before the Christian era, yields little more than a few fragmentary representations of musical instruments which are indicative of the early existence of music, music historians have, in recent years, tended to cease their perhaps interesting but ultimately futile speculations as to the beginnings of music and to refer the whole matter of origins to the comparative musicologist. The latter considers not only the historical evidence but also the primitive, exotic, and folk music of today; the musical development of the individual; and the physical, physiological, psychological, and aesthetic factors that are basic to the very existence of music. From the study of various aspects of the amassed evidence he reaches many suggestive conclusions, of which a few may be cited. He concludes, for example, that the enjoyment of music is inherent in man's nature; that the physiological response to rhythmized patterns of sound is deep-seated, being based upon natural laws that may be scientifically investigated; that under emotional stress, highly inflected speech tends to merge into musical utterance; that music functions naturally in courtship as in most ceremonial occasions; that music may be partially accounted for as an overflow of nervous energy; that in play as in work there are countless situations in which music affords a natural accompaniment to bodily movements; that the physical world affords practically unlimited possibilities for the production and control of sounds so that they may be organized into tonal-rhythmic patterns that have a profoundly moving effect upon man; and, finally, that the basis for these effects is to be found in man's psycho-physiological and aesthetic nature.

Thus, while early writers on the history of music tended to attribute a divine origin to music, and while 19th cent. evolutionary thinking tried to establish definite stages of development in the beginnings of music, such as Rowbotham's *drum, pipe,* and *lyre* stages, modern musicologists deal with the problem of origins by revealing the evidence of the existence of music in the earliest known civilizations and by pointing out the biological, social, and other factors that are indicative of the inevitability of music in the life of man. See Allen, Warren D., *Philosophies of Music History,* New York, 1939; Haydon, Glen, *Introduction to Musicology,* New York, 1941; Spencer, Herbert, "On the Origin and Function of Music," *Essays,* Vol. I, London, 1868; Stumpf, Carl, *Die Anfänge der Musik,* Leipzig, 1911; Torrefranca, Fausto, "Le Origini della musica," *Rivista musicale italiana,* Vol. XIV (1907); Wallaschek, Richard, *Anfänge der Tonkunst,* Leipzig, 1903. —G.H.

**music printing and engraving.** The various methods of reproducing musical notation form a development which may be considered in three broad stages: first, the manuscript; second, the early hand-press; third and last, the modern automatic press. The labor of one scribe could provide only one copy at a time. The editions of the early hand-press were relatively small and expensive. The output of a modern press is hardly limited at all save by the demand for its product. The significance of this development is implicit in these facts. The restricted output of the earlier processes is coupled with a restricted circulation of the music printed due both to the rarity of copies and their great cost. The unlimited output of later methods is inseparably associated with the spread of popular education and culture through the circulation of correct and cheap copies of the musical masterworks of all periods.

As would be anticipated, music printing lagged somewhat behind the printing of books. Thus, in the earliest works that re-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

quired musical illustrations printers resorted to makeshift devices. In the earliest volume with music (*Collectiorum super Magnificat*, J. Charlier de Gerson, 1473) the notes only, not the lines are printed. The lines were to be filled in by hand, and since no special type was available for the notes, the printer employed stamps which were ordinary type reversed so that they printed a solid black rectangle.

In other cases a blank space was left, and both notes and music had to be filled in by hand. As the need for musical type began to be felt, two styles appear: the roman with a basic square note-shape and the gothic with a lozenge-shaped note. The gothic form appears first in the *Grammatica Brevis* of Franciscus Niger, Venice, 1480, printed by Theodor of Wurzburg.

Another device of the early printer was based on the technique of the wood engraver. In this method the musical notation, notes and staves as well as the surrounding border, is cut from a single wood block. The musical examples in the *Theoricum Opus* of Franchinus Gafurius were printed thus in the second edition (1492, printed by Mantegatius of Milan).

Secular music printing begins with the *Grammatica of Niger*. Another important early imprint is the *Legend of Saint Ursula* (1497, printed by Kustler of Strassburg) which is notable for the fact that it contains the melodies of secular songs.

Another type of publication peculiar to the Renaissance was the school play. The *Scenica Progymnasmata* of Reuchlin published in 1498 in two different editions deserves special mention in this group as the first published play with printed music. Wood blocks were evidently costly to produce and were preserved with care. When a book was republished the same blocks for musical examples were frequently used. The songs in praise of the Emperor Maximilian by De Opitiis (Wittenberg, 1523) shows the wood block technique used in a festival volume.

Many early ecclesiastical books were printed in two colors. The notes were printed in black on a four line staff which, together with the border and initials, was in red. This practice was probably derived from the practice in manuscripts of drawing the line of the staff indicating F or C in red so as to facilitate the reading of the music. The earliest work of this kind was the *Psalterium of* 1457 printed by the famous Gutenburg in collaboration with Fust and Schoeffer. This volume, however, shows a transition to the two color process since three of the four staff lines are printed in black, while the fourth or red line as well as the notes were left to be filled in by hand. The fully developed process necessitated two impressions, but printers had already acquired skill in this technique which had been employed in books of other kinds since approximately 1460. The exuberance and variety of the tone symbols, the neumes, was gradually reduced to a few basic types. Most volumes in red and black were those containing the music for the services of the Catholic Church: the *Psalter, Missal, Gradual,* and *Antiphonal.* The Roman style, employed first in Italy, has remained in use for liturgical books up to the present day. In the 15th cent., however, the so-called Gothic style was employed with equal frequency. Here we must distinguish two types of note: the simple lozenge and the lozenge with a straight or curved stem (the horseshoe nail and horseshoe forms).

The problems involved in printing polyphonic music were somewhat different. Contrary to modern custom music in several parts for voices was printed in part books, each book containing the music for one voice. Ottaviano Petrucci da Fossombrone, the pioneer in the printing of secular part music and the inventor of a method of printing music from movable type, published his *Harmonice Musices Odhecaton A* in Venice in 1501. This publication which contains French chansons and Italian canzonets was followed by *Canti B* (1502) and *Canti C* (1503), and these by a long series of motets and masses. His later experiments in printing instrumental notation in the form of tablature have left no results which survive.

Though music which Petrucci had printed from movable type possessed both clarity and elegance of style, he nevertheless employed two or possibly three impressions to obtain this result.

It was a Frenchman, Pierre Haultin, who first printed music in a single impression by combining in a single character the note and the adjacent portions of the staff. Previously this had required two impressions, one for the staff and a second for the notes. Haultin was associated with the famous French publisher Attaignant, and the first publication printed according to his system was a collection of chansons which presumably appeared in 1527. This method spread to other parts of Europe and was employed with notable success by Antonio Gardano.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

However, the method was most assidously practiced in France and in 1552 the Ballard family obtained a patent which gave them the sole right to print according to this method, a right which they were able to retain to the end of the 18th cent. Early impressions of Haultin had retained the diamond-shaped Gothic notes. The round headed note which is currently employed first appeared in a collection of music by Elzear Ganet printed by Etienne Briard in 1532-34 (three volumes). This system of single impression printing was ill adapted to chordal music or to music which was florid in character, employing many notes of short duration.

The immediate answer to this difficulty was found in an application of an ancient art. Copper engraving had long been known as a method of reproducing designs or pictures. Its first application to music, as far as is known at present, was in the *Diletto spirituale* of Simone Verovio, published in Rome in the year 1600. The method was simply to copy the music in reverse on a copper or other soft metal sheet with the aid of the graver and other implements. The hollows thus formed were filled with printers ink and this, when run through a press, transferred the inked design to a superimposed sheet of paper.

A possible hint as to the manner in which the transition from engraved picture to engraved sheet of music was effected may perhaps be found in the so-called **picture motets** from the Low Countries in which musical performances are depicted including the part books from which the pictured singers and instrumentalists are reading. Early examples of this kind and the title pages of certain works from the Netherlands in which musical notation is incorporated into the design surely suggest a possible transition from decorative engraving to the engraving of musical notation. In engraved music note-heads were round. Groups of notes of uniform time value were connected by engraved lines instead of being represented as single notes each with its own flag. A work of the first importance among early examples of Italian music engraving is the *Toccate e Partite* of Girolamo Frescobaldi, engraved by Blancus for Borbone, Rome.

In England, though Thomas Morley had been granted a monopoly for engraving music in 1598, the first volume of music did not appear till the years 1609-10 when the *Fantasies* for viols by Orlando Gibbons were published. At a later period (1683-1720) Thomas Cross engraved almost all the music produced in England, including the works of Henry Purcell.

The tardy appearance of engraved music in France was due to the fact that the Ballard family which controlled the printing of French music found it simpler to continue printing with type. The conservative trend thus fostered was so fixed that even when a score of Lully was engraved (*Phaeton*, 1675) by H. de Baussen, the Gothic lozenge-shaped note heads characteristic of French musical typography were retained. Later, however, the round note-head was adopted

The next change in music printing was due to the English publishers Hare and Walsh. For motives of economy sheets of pewter were substituted for copper and the process was further facilitated by punching or stamping such symbols as clefs and note heads, the remainder being engraved as before. Cross, the leading English engraver of the period, was a bitter opponent of the new method, going so far as to engrave a warning on one of his own plates, "Beware of ye non-sensical puncht ones". Nevertheless, the process combining punched and engraved portions became and remained a standard method.

If the method of printing from type did not entirely disappear, this was due to improvements effected by Johann Immanuel Breitkopf, improvements which were in part paralleled by the work of Fournier Le Jeune in France. The latter could make no headway in putting his method into practice due to opposition from the holders of the Ballard monopoly. The musical symbols were divided into parts and were combined with portions of the staff. These units could be assembled as desired. Type setting was laborious, and the number of type forms required was very large: over three hundred in Breitkopf's method; so that, although it was considerably used during his own day in Holland and Germany, subsequent use has been restricted to volumes where the amount of music is rather small in proposition to the amount of text, such as hymnals, song books, and theoretical works. The first work printed by this process was an aria which appeared in 1754.

Breitkopf's work consisted in a more effective adaptation of the ancient art of printing to the special demands of music printing. Lithography, however, was based on quite a different principle. It was in the search for a cheaper medium than the copper plate that Alois Senefelder turned to the so-called Solnhofen or lithographic stone. In early attempts the music was written directly on the stone

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

with a special ink. The remainder of the stone unprotected by this ink was attacked by an acid bath which left the characters in relief. The first example of music printed by this process was a *Feldmarsch der Churpfalzbayer'schen Truppen,* issued in 1796.

Two years later the process was improved. The stone on which the music was written in reverse was treated with a solution of gum arabic, acid and water. Printer's ink when applied to the stone was attracted only to the ink-covered portions and thus an impression could be obtained with the aid of a printing press. In spite of much prejudice on the part of musicians the new process had a powerful argument in its favor since engraved music was three or four times as expensive as lithographed music. Thus lithography became the usual mode of publication for popular songs of the early 19th cent.

Modern music printing is likely to combine elements from earlier processes. The original copper plate is prepared by punching and engraving. The text of vocal compositions may be either punched or printed in later. A proof in lithographic ink is taken from the copper plate and is transferred, not to a stone, but to a metal plate with a specially prepared surface. It is this second plate which is used in the actual printing. Copies may either be printed directly from the plate or, in the offset process, the plate transfers its impression to a rubber blanket, and the latter actually serves to print the page.

The development of music printing may be regarded as the progress of technical development and democratic education marching hand in hand. This development proceeds from the limited edition of the hand press to the limitless production of the modern press, from the costly product of the hand craftsman to the cheap mass output of the modern machine press, from an exclusive and aristocratic art to one which may become a people's art. This is a development which technological skill alone has made possible. Our admiration for the typographical beauty of the masterpieces of early music printing should not blind us to the fact that the basic function of printing is wide-spread diffusion.

**Mycenean architecture.** See Aegean architecture.

**Mycenean art.** See HELLENIC ART.

**myrtle.** In Greek pottery, a decorative pattern having small pointed ovate leaves arranged opposite each other on the stem.

**mystery play.** See THEATRE.

**myth.** Two contrasting meanings belong to myth: legendary fiction and poetic truth. The double delusion that myth means only fiction and that all that is not science is myth has prevented multitudes from discovering the depths and the delights of mythical art.

Anthropologists regard myth-making as characteristic of human nature. Plato and Schelling proved that myth is indispensable for art. "The Platonic myth indicates how the mind necessarily completes through imagination its unfinished knowledge." (W. E. Hocking, orally.) Schelling viewed myth as the ancestral union of poetry and philosophy. Here in imagination man freely builds for himself the word-pictures needed to express his feelings about ultimate concerns, and to enjoy himself in the process.

The ancient Greeks used *mythos* and *logos* alike for speech, word, or report, without reference to truth or untruth. *Mythos* meant also unspoken thought, purpose, plot, story, or fable. Pindar would not ascribe cannibalism to the gods, but only beautiful acts, consistent with divine dignity.

Thus unexpectedly we discover that myths may be true. Indeed their artistic importance lies in their power to express a kind of truth

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

about human values which cannot be embodied in prose or in any other art form.

Aristotle's use of myth may unlock its philosophical depths: "The *mythos* (plot) is the first principle and as it were the soul of tragedy." (*Poet.* vi, 14). The poetic myth is a drama within the soul. But the mythical stage is the mind; the narrator himself carries forward the action in his imagination. The myth is a picturesque and personalized story designed to enhance some important feeling about natural wonders, destiny, or divine things.

This psychological-intuitive approach, coupled with a sympathetic anthropology and an earnest faith, provides the best method for interpreting myths. Historical, allegorical, and philological methods have added much to the science, but little to the artistic appreciation, of myths. **Artistic myth** means a kind of spontaneous narrative in which psychic realities, especially fears and hopes, are expressed in concrete imaginative language, usually in dramatic form.

Myth assumes four forms in art:

A. Myth proper:
   1. *Primitive myth,* the prototype of poetry.
   2. *Art myth,* perfected poetic narratives, like Plato's myths.

B. Derived myths:
   3. *Symbolical myth,* conscious purposive inventions: allegories, parables, fables.
   4. *Mythical transformations:* artistic works which incorporate original mythical materials, such as Wagner's operas or Dante's *Divine Comedy.*

Plato loved the myth, and cast his deepest insights into unique art myths, not only because they are aesthetically delightful but because no other art form could express his cosmic visions. Urban asserts in *Language and Reality* that the mythical form is indispensable for the expression of religious views because it is "a primary and unique way of apprehending reality".

As long as man wonders about his future and the mysteries of existence he will demand the "mythical supplement" to science. "Myths there must be, since all visions of the future must be clothed in imagery." (Hocking, *Fortune,* February, 1942.) Much of myth is artistically prefigured history, utopias that man deeply wishes somehow to happen, such as the Messianic Age or the Kingdom of God. See B. Malinowski, *Myth in Primitive Psychology,* 1926; F. C. Prescott, *Poetry and Myth,* 1927; J. A. Stewart, *The Myths of Plato,* 1905. —R.F.P.

**Nachayama yaki** (Jap.). Pottery made in Tosa province.

**naga** (Skr.). The serpent. An important element in Oriental art, esp. in Cambodia and India.

**Nagasaki school** (Jap.). A school of painting originating at Nagasaki, after the Chinese manner.

**Nagasaki ware.** Lacquered porcelain, first produced in the vicinity of Nagasaki, Japan, thus the name. The decoration was applied to glazed porcelain blanks by lacquer artists. —J.A.M.

**nakago** (Jap.). The tang, or the shaft that fits into the handle of a sword.

**Nanga school** (Jap.). A style of painting depicting genre subjects in an idealistic Chinese manner.

**naos.** See HELLENC ART; Hellenic style.

**naphtha.** Among the diluents for oil as a painting medium, naphtha or some kind of petroleum spirit ranks second to turpentine. There is still some confusion between petroleum naphtha and the coal-tar naphtha which is a crude distillate containing chiefly benzene and its homologues. The petroleum thinner, known also as benzine, gasoline, and mineral spirits, is prepared in a range of different evaporation rates, flash points, and densities. Active on oils while these are still in the fluid state and on waxes as a solvent, naphtha has little solvent effect on resins, except dammar. Historically, it has been known since ancient times, but seems to have had little use in painting until the 19th cent. —G.L.S.

**Naples yellow.** Now rare as a painter's pigment, this lead antimoniate seems to have been known and used moderately during the Middle Ages and the Renaissance. As a glaze for ceramics, it has been familiar to potters since Babylonian and Assyrian times. It is yellow to orange in color and is made synthetically from the salts of lead and antimony—G.L.S.

**narrative lyric poetry.** See POETRY.

**narrative poetry.** See POETRY.

**narrator.** In the earlier passion plays and in oratorios, the singer of the narrative text. See RADIO DRAMA.

**narthex.** The portico of ancient churches; one side or member of the atrium or outer court surrounded by ambulatories.

**nashiji** (Jap.). Term applied to lacquerware when gold is sprinkled on a lacquered surface through a screen and, when dried, rubbed down, thus producing an allover gold-flake pattern. —J.A.M.

**Nashki script.** See ISLAMIC ART.

**Nasta 'liq script.** See ISLAMIC ART.

**national planning.** See CIVIC PLANNING.

**national song.** See song.

**natural.** In masonry: Term applied to stone as it is found in its natural form and shape.

**natural dance.** The school of *natural dance* arose in the U.S.A. in the last part of the 19th cent. It held that dance was an expression of nature and that all the forces

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

of nature and of man are revealed in movements manifesting the universal laws of rhythm. Its most enlightened advocates turned to the plastic arts of the Greeks—not so much to imitate their gestures, as to rediscover in them the expression of nature and to dance under the inspiration of the Greek ideal. Their dancing interpreted nature themes and natural qualities with what was considered to be natural movements. It was a return to nature, but unfortunately many of the followers were without conviction or a clear understanding of its real meaning. As a result there was much dancing that was imitative only of the usual aspects of "nature movements" instead of being motivated by an inner and unique responsiveness to the forces revealed by movements of natural phenomena. Since natural dance defied the technical principles of the classic ballet, form was at the mercy of the spontaneous naturalistic interpretation of the dancer. With no inner logic of its own, dance was dependent upon music both for inspiration and structure. It is at this point of dance evolution that **interpretative dance** appeared, defining dance as the expression of the dancer's interpretation of moods and ideas created by music. The influence of this new theory of dance spread to Europe and was instrumental in affecting changes in the dancing of France, England, Italy, Russia, and Germany. "Natural dance" was an awakening to the further enlarged possibilities and achievements to be realized in the more mature art dance of today.

—M.N. H'D.

**natural harmonica.** See ACOUSTICS.

**natural tones.** The natural harmonics of an instrument.

**naturalism.** The doctrine that nature should be represented objectively, without interpretation or editorializing. The representation of the natural in the sense of that which exists apart from an uninfluenced by man.

(1) From a formal point of view naturalistic art has a minimum of decorative or expressive distortion of appearances. Naturalistic painting approximates camera vision; sculpture approximates a cast taken from the model directly; literature approximates scientific prose description. Impressionism (q.v.), however, is also a form of naturalism, since it aims to report objectively what the eye sees at a momentary glance.

So far as form is concerned, an artist may be a naturalist though his subject matter consistently evoke sentimental, romantic, or idealistic associations, e.g. Holman Hunt, Millais, Watts, Meissonier, Rosa Bonheur, Landseer, Böcklin, and Saint-Gaudens. Other naturalists include painters Courbet, Manet, Monet, Pissarro, Sargent, Homer, Eakins, Sorolla, Zorn, Liebermann, Vermeer, Hals, and Caravaggio; sculptors Rodin, Barye, Falguière, Hildebrand, and Dallin; authors Zola, Flaubert, de Maupassant, the de Goncourts, Brecque, Sinclair Lewis, Dreiser, Hemingway, Faulkner, Stephen Crane, and James Farrell.

To use the language of philosophy, formal naturalism parallels nominalism and represents the "particular" rather than the "universal" (artistic idealism) or the "universal in the particular" (artistic realism). As might be expected, therefore, the doctrine flourished when belief in the reality of "particulars" was most current in philosophy, in the Hellenistic and Roman period of antiquity and in the late 19th cent. Sculpture of the type of the *Laocoon,* the *Borghese Warrior,* the *Old Market Woman* in the Metropolitan Museum, N. Y., and most Roman portrait busts of the Republic and first two centuries of the Empire are examples of ancient naturalism. In graphic arts, the *Odyssey Landscapes* in the Vatican Museum and the *Battle of Issus* mosaic in the Museum of Naples may be designated as naturalistic, and these are representative of the period.

19th cent. naturalism is the end product of the drive for illusionism (q.v.), which began in the early Renaissance and paralleled the rise of science and the disintegration of religion. Influenced by the development of the camera and the appearance of materialistic philosophy, it reached its apogee in the 2d half of the 19th cent.

(2) In the most complete sense, artistic naturalism is not merely a matter of form, but also of content, and implies a naturalistic philosophy. Courbet, Manet, Rodin, Zola, Flaubert, de Maupassant and other minor French artists and authors of the late 19th cent., and a number of 20th cent. American authors, exemplify this comprehensive use of the term. Their position is analogous to positivism in philosophy and may be described as the scientific method applied to literature and the graphic and plastic arts. Some of these artists were called realists (q.v.) and some of them used this term to describe their doctrine, but their meaning was the same as that here outlined. They programmatically presented with cold indifference and

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

detachment a literal transcript of the physical world about them, and refused to cultivate the world of imagination, to believe in anything not present to the senses, to seek any hidden meanings, to minimize the more disagreeable, vulgar, sordid, decadent, coarse, and morbid aspects of their world, or indeed to alter the physical world in any manner or for any purpose. Thus, their doctrine opposed alike the cultivation of classic beauty in the manner of the contemporary neo-classicists (q.v.) and the search for novel and emotive fragments of form and subject indulged in by the romanticists (q.v.). Rejecting academic rules of drawing, painting, modelling, and composition, they prepared the way for a new subjectivism in the several arts, which arose in the last two decades of the century under the name of post-impressionism (q.v.) in painting and symbolism in literature.

(3) Naturalism is occasionally loosely applied to all original forms of modern art since the time of Courbet and Zola, referring only to naturalistic content without consideration of form. In this vague sense it is employed as the antithesis of humanism in art and letters. Hence it includes artists and authors of such diverse style as Toulouse-Lautrec, Matisse, George Grosz, Picasso, Max Beckmann, Salvador Dali, Epstein, Belling, Gertrude Stein, John Dos Passos, Sherwood Anderson, and Jack London, all of whom, in contrast to humanists, depreciate man in dignity, nobility, and ethics, and treat the order of the universe as mechanistic or deterministic rather than anthropocentric and teleological.

(4) Naturalism is sometimes applied to a period, style, or artist in a comparative sense, as with reference to an art which precedes or follows, or by comparison to a more stylized art of another era; as when the painting of Middle Minoan III is compared to Late Minoan III, or when Latin illusionism of the 4th cent. is compared to East Christian art of the same century, when Greek sculpture is contrasted with that of Egypt, Ingres with Matisse, Western art with Oriental, or any comparatively representational art with one of symbolic ideographs. In each case the art first mentioned is said to be (comparatively) naturalistic, even though it is recognized as non-naturalistic in a more absolute sense of the term by comparison with Hellenistic and 19th cent. illusionism.

—L.D.L.

**nature symbols.** See PRIMITIVE ART.

Navaho art. The Navaho were Athapascan nomad hunters from northwest Canada and Alaska who began infiltrating into the Pueblo country and raiding the villages six or seven hundred years ago, and were a contributing cause to the concentration and later the migration of the Pueblo peoples. Contact with the Pueblos gave the Navaho a knowledge of corn culture, weaving, possibly the art of sand painting, and, most important, the acquisition of the horse, sheep and goat brought by the Spaniard. These were the chief transforming elements that enabled the assimilative Navaho to develop his characteristic semi-nomadic culture pattern. Though the high plateau country which he had appropriated in northern Arizona, New Mexico and southern Utah furnished sparse vegetation for grazing and the horse gave him mobility for wide ranging, still the acute need for rain colored his legends, ceremonials and symbolism. In winter the family lived in a substantial hogan (q.v.); in summer, under shelving rocks or in a loosely constructed brush shelter. The men farmed on a small scale or wandered with the flocks while the women wove at the looms set up out-of-doors near the hut.

With the introduction of sheep, weaving, from c. 1700 A.D., became one of the chief crafts which grew out of the needs of daily living: warm blankets for home, man and horse. This was entirely a woman's craft. The designs at first consisted of simple stripes limited in color to natural wools and a few hues obtained from native dyes, such as indigo, to which red was added from ravelings of English or Spanish baize, called bayeta. To these striped patterns were added simple geometric motifs such as zigzags, diamonds and terraced patterns. About the middle of the 19th cent. the so-called Chief blankets, in their weaving, texture, color and pattern, constitute some of the finest textiles of aboriginal America. Later in the century, with the introduction of Germantown yarns and aniline dyes the craft deteriorated and turned toward the making of rugs with borders, in response to trade requirements of the white man. Early in the 20th cent. occurred a revival of the older style based on stripes and more conservative color.

Silversmithing the Navaho learned from the Mexicans about 1850. He obtained his material first from Mexican and American dollars, later from sheet and ingot metal. By hammering, molding, polishing, engraving and stamping, though always with primi-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

tive tools, he fashioned buttons, bracelets, beads, pendants and mountings for belts and bridles which not only served as ornaments but revealed his economic status, judged by both quantity and quality of workmanship. Designs consisted of engraved lines or geometric shapes, or of motifs of Mexican origin, and show the same simple vigor as those in the blankets.

Probably the most unusual art characteristic of the Navaho was sand painting (q.v.), an American abstract expression that is thoroughly indigenous as well as rich in content and design. Sand painting, or dry painting, is but one element in the elaborate ceremonials of the Navaho in which are expressed by costume, drama, dance and song his rich complex mythology, significant of his relation to great cosmic forces. Much of this ritual reveals highly imaginative poetry. The function of the ceremonials, which last from two to nine days, is three-fold: to cure or prevent disease; to invoke the gods for rain, fertility and the general well-being of the tribe; and to provide a semi-nomadic people social contact with the tribe. As a unit they constitute one of the great coordinated, autochthonous art expressions of America. See Charles Amsden, *Navaho Weaving,* 1934; Washington Matthews, *Navaho Legends,* 1897 and *The Night Chant,* 1902; Arthur Woodward, *A Brief History of Navaho Silversmithing,* 1938. —H.G.

**Navaho rugs.** First made as robes by Navaho Indians. Now used as rugs for the trade. Quality is judged by smoothness of weave, dyeing and blending of the colors and beauty and originality of the design. —B.E.J.

**nave.** In basilican and cruciform churches, the part that rises higher than the aisles flanking it and has, usually, a clerestory.

**nave arcade.** The series of columns and vaults dividing the nave of a cruciform church from the side aisles.

**naviform.** Boatshaped.

**Nazarenes, the** (Ger. *Nazarener*). On July 7th, 1809, the painters Overbeck, Pforr, Wintergerst, Hottinger, Vogel and Sutter, students of the Vienna academy of art, formed the Order of St. Luke as an expression of their dissatisfaction with the teaching at the academy. In the fall of 1809, when the Vienna academy, which had been closed because of the war, was reopened, Overbeck and Pforr, although not officially expelled, were refused readmission.

Overbeck and Pforr went to Rome in October 1809 and lived, beginning September 1810, in the deserted monastery San Isidoro on the Pincio, calling themselves the *Fratelli di San Isidoro.* They were joined later by Peter von Cornelius, Wilhelm von Schadow, Philipp Veit, Julius Schnorr von Carolsfeld, Johann Scheffer von Leonardshof, Joseph Ritter von Führich, Eduard von Steinle, Karl Begas and others. The name *Nazarener,* with ironic connotations, was given to the members of the group by other German artists in Rome who were somewhat annoyed with their religious zeal and with their efforts to renew art by means of ethical teaching. After the successful work of the group—the frescos in the *Casa Batholdy,* 1816; and in the *Casino Massimi,* 1817 to ca. 1830—the name gradually lost its ironic connotations; it is now used as a purely descriptive term.

The aim of the Nazarenes was a renewal of art on the basis of Christian (i.e., for them Roman Catholic) ideals and principles; they were opposed to the academies of art because, in their opinion, the teaching in the academies fostered superficiality and lacked the human and personal intimacy of the master-apprentice relationship which they considered to be a necessary basis for the teaching of the arts. The Nazarenes furthermore protested against the emphasis of purely artistic qualities and they held that art should primarily serve the expression of noble ideas (preferably religious). In order to achieve their aims the Nazarenes organized themselves into a group which was a combination of a monastic order and a medieval guild. In the beginning they took as their artistic example the works of the early German and Italian painters; later they were strongly influenced by Perugino, Raphael and Michelangelo. Stressing the collectivistic aspects of the medieval artists' guilds, they sacrificed part of their individuality in favor of the work of the group. Examples of works carried out in such a group spirit are the frescos in the *Casa Bartholdy,* 1816, since 1887 in the National Gallery, Berlin, and the frescos in the *Casino Massimi,* 1817—ca. 1830, Rome.

Many of the Nazarenes were appointed professors at German academies of art. However, their teaching met with just as much criticism as they (the Nazarenes) had once voiced against their own academic teachers. The reasons for the relatively quick decline of the Nazarene movement can be seen in

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

the fact that the Nazarenes in their program over emphasized the moral and religious aspects of art and failed to recognize sufficiently the aesthetic and artistic aspects. The strict rules of the order of St. Luke, which were applicable to a small group of religiously inspired artists, were inapplicable to the larger institutions of the academies of art, and the Nazarenes had to compromise in their teaching in institutions which, after all, specialized in artistic training. Furthermore, the **Biedermeier** (q.v.) period was rather opposed to the romantic—heroic style of the Nazarenes and a fusion of their style with the Biedermeier art resulted in a compromise which, from the present-day point of view, was not too successful (see Düsseldorf, school of).

Ideas similar to those of the Nazarenes were taken up again by the Pre-Raphaelite Brotherhood (q.v. Pre-Raphaelite Brotherhood) and it is possible that the Pre-Raphaelites were influenced by the Nazarenes. See GERMAN ART; Margarete Howitt, *Friedrich Overbeck. **negative carving** (a technique in concave or sunk relief). This technique, because of its striking effects in achieving plastic form in low and very low relief, has been used since the Babylonian era. It is simply reversed carving in which the form is cut into a surface instead of projecting from a surface and may be used as a hollow relief or as the mold for a bas-relief. Especially suitable for smaller designs, it has been used successfully in the creation of medals, coins, plaques, relief portraits, sculptural jewelry and as a guide in glass engraving, to which it is related. It may be used in carving sculptural designs into ceramic molds; the technique allows the sculptor the creation of quick sketches of contemplated larger reliefs for the study of scale, composition, light and shade. It is possible to make rapid nature studies in negative carving, by working directly from the model and it could be used in certain types of illustration and commercial art through photographic reproduction. The usual material for negative carving is a smooth plaster surface of fine grain. (Harder to carve, but more precise is a slab of slate or lithographer's stone, for which hard, sharp tools are needed.) As tools on the plaster surface small plaster carving and retouching tools, gouges, scoops and rifflers may be used. Having explored this technique, the sculptor is well able to adapt some of his tools to this method by bending and filing them into more practical shapes.

The procedure is as follows: On the aforementioned plaster slab (slightly moistened) the outlines of the desired composition are traced or drawn in reverse, or mirror image. Throughout this procedure it must be remembered that design as well as form are created in reverse (by casting, the desired convex form will be attained). A design having an animal on the right side and a figure on the left, has to be traced and carved with the animal on the left and the figure on the right side; similarly, all lettering has to be reversed.

With larger sized tools one proceeds to scoop out the major parts of the figure (or figures, portrait, etc.) in their relative relief value and in order of size, so that the traced outline is not disturbed. (In a figure composition, the body, void of all detail, is scooped out, then follow arms, legs and head, all in their basically geometric form.) In order to check the relative depth of the various parts, a squeeze is made with moist clay or soft plasteline. For a clay squeeze, the plaster surface should be dry; for plasteline, it must be wet. During the procedure it is best to make as few squeezes as possible because of their tendency to smudge or grease the plaster. When satisfied with the general depth reached, or the plastic value of the crude forms, the details may be superimposed. Where arms, legs, draperies cut across a figure, the body must be well carved out before these parts can be carved. It is an important part of this technique that all forms are carved in order, according to size (for a head an egg-shaped form is scooped out, then details are cut into the egg-shape, as forehead, eyes, nose, mouth, etc.; or on a hand, the full part is carved before the fingers may be added).

When carving has progressed beyond the primitive stage, the work can be checked easily. The plaster is held up, allowing light to fall in on one side; closing one eye, the concave design will appear shortly as convex,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

an interesting optical illusion, which shows up errors at once. By checking in this manner it is possible to complete the work with only few squeezes.

After completion of the principal parts, final details, such as hair, draperies, clothing folds and other accessories are added. Where the edge around the design (circle, square, etc.) is to be raised, it should be carved in during early stages of the carving in order to avoid readjustments of the major parts. When the composition has been checked through a final squeeze, it can be cast like any plaster mold.

Because everything in this technique is reversed, some difficulty at first may be expected; once used to it, one can work rapidly. A clearness of form and precision of detail, difficult to obtain in other techniques, may be achieved. —C.L.S.

**Neo-classic architecture.** A term applied to the revived classic architecture in Europe and the U. S. A. of the latter part of the 18th and early 19th cents. It is not to be regarded as a superficial or a reactionary manifestation, but one of profound and lasting consequences. The revelations of the archeologists of the 18th cent. in Spalato, Pompeii, Athens and elsewhere, and more particularly the publications of Stuart and Revett and the brothers Adam merely served to foster and orient the reaction against the expiring renaissance. The critical writings of Winkelmann and Lessing (1717-1768) had laid the intellectual foundation, and the actual contact with the age of Pericles established through the Elgin Marbles gave energy to the movement, already apparent in the refined severity of the Louis XVI style and the revolutionary experiments of Ledoux and Boulee.

The earliest exponents of the neo-classic, Sir John Soane in England and Karl Schinkel in Germany were both men of very progressive ideas. Both were ardent advocates of contemporary planning for use and employed the neo-classic as a concession to the popular demand for a classical envelope. Soane's Bank of England and the Schinkel Museum in Berlin are inherent with a vitality which their exterior aspect is far from conveying.

In both England and Germany, however, the tendency swung from reality toward a purely archeological interpretation of classic forms. Smirke's British Museum and von Klenze's Pinakothek, Valhalla and Glyptothek in Munich have little to commend them other than the inevitable dignity of their classical envelope.

Nevertheless, H. L. Elmes in St. George's Hall, Liverpool, completed as late as 1854, embodies the most successful example of neo-classicism in England.

In France the neo-classic, except for Napoleon's Romanic buildings, remained free from the virus of archeology and displayed itself rather in a suave refining of lines and contrasts, the accentuation of the horizontal and the employment of the Greek orders not as a dominant note but secondary to the contemporary features of the design. Labrouste's Bibliotheque St. Genevieve and Hittorf's Gare du Nord (1863-4) bear witness to the vitality of the French neo-Grec.

But nowhere did the neo-classic find a more hospitable soil and flourish with a more genial adaptability to new conditions than it did in the 1st half of the 19th cent. in the U. S. A. In public buildings, such as the U. S. Treasury in Washington, the Patent Office, the Sub-Treasury in New York, it followed perhaps too closely the restraints of the temple form and, as in England and Germany, achieved a somewhat stilted and fortuitous dignity, but in the newly developing region from the Alleghenies to the Mississippi, from the Great Lakes to the Gulf of Mexico, the neo-Grec style was appropriated to the domestic requirements of the time. The old mansions of Natchez and such lovely examples as Berry Hill, Va., Andalusia, Philadelphia, the Boody House on Seneca Lake, the plantation houses near New Orleans, to mention but a very few, exhibit no casual affectation following a transitory fash-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

ion but constitute an expression of wholehearted sincerity in the adoption of the canons of classic culture.

In our day we are no longer moved to embellish our homes with Greek columns, but the drift to simple forms, integrity of surface and continuity of line are a direct inheritance from the refinement of taste inculcated through the medium of the neo-classic style. See *Architecture Through the Ages,* Hamlin, 1940; *"An Outline of the Career of Sir John Soane," R. I. B. A. Journal,* Series 3, XXIX, 1921-22; *Domestic Architecture of the Early American Republic—The Greek Revival,* Howard Major, 1926. —L.H.

**Neo-classicism.** A movement in painting, sculpture, and architecture, current in the last quarter of the 18th cent. and 1st half of the 19th cent., requiring the imitation of the outward form of Hellenic, Hellenistic, and Greco-Roman art and architecture. It was not truly classic in content, but on the contrary was romantic or academic. The forms were superficially analogous to those of late antiquity, however, and hence the term "pseudo-classic" is often used interchangeably with neo-classic.

The movement was at its height during the French Revolution and the Napoleonic period. As the official and popularly approved style, it fought the rise of rebellious romanticism from about 1820 to 1850, and thereafter throughout the 19th century remained entrenched in the academies of Europe and America, opposing realism, impressionism, and post-impressionism as it had earlier defended itself against the heresy of romanticism.

Neo-classicism developed, in part, through the influence of 18th cent. antiquarianism and classical archeology, best personified in the German art historian Winckelmann. Politically and culturally, it represented the reaction away from the luxury, license and aristocratic taste of the age of Louis XV, and was associated with the Spartan and stoical Roman virtues admired in the rise of the Third Estate during the French Revolution and the period of Napoleon. This admiration of an enviable era of the past was basically romantic, however; and in the illustrations of the heroic events and mythological incidents of antiquity, and in the imitation of ancient customs, dress, temples and triumphal arches, this romanticism of content is scarcely concealed by the pseudo-classic forms.

Hellenistic, Greco-Roman, and Roman prototypes were first used, and little distinction was made between Greek and Roman characteristics and qualities in art. As the 19th cent. progressed and knowledge of antiquity increased, the fashion changed gradually to an appreciation and comparatively feeble imitation of Hellenic forms.

Painters imitated antique sculpture since so little ancient painting was known. Extant examples at the time neo-classicism flourished were restricted almost exclusively to those paintings uncovered in partially excavated Pompeii. Some of the painters were also influenced by Italian High Renaissance and baroque artists, esp. Raphael and the Carracci. In contrast to romanticists, neo-classic painters emphasized drawing and form rather than color and expression, and easily succumbed to academic formulae for success. The chief neo-classic painters were, in France, David, Ingres, Gérard, Guérin, Prud'hon, Couture, Chasseriau, Cabanel, Henner, Bouguereau; in England, Lord Leighton and Alma-Tadema; and in America, Allston, Thayer, Vedder and La Farge.

The major neo-classic sculptors include the Italian Canova, the Dane Thorwaldsen, Flaxman in England; in France, Pradier, Chaudet, Cortot, Bosio, Caldelari, David d'Angers (in part), Foyatier; in Germany, Dannecker and Schadow; in Sweden, Sergel; and in America, Powers, Greenough, Crawford, Hosmer, Palmer, Rogers and Rinehart.

In architecture, the forms of Roman temples, basilicas, baths, and other public buildings, and occasionally the forms of the Greek temple, propylaea, and stoa were adapted to all modern uses, whether for churches, banks, high schools, museums, legislative halls, town halls, railroad stations, palaces, or homes. Leading neo-classic architects include Vignon, Percier, Fontaine, Chalgrin, and Brogniard in France; Langhans, Schinkel, and Von Klenze in Germany; in England, Soane, Elmes, Hamilton, and Smirke; in Italy, Selva and Bianchi; and in America, Thomas Jefferson, Bullfinch, Hooker, Thornton, Hallet, and Latrobe, and even such contemporary architects as Bacon and John Russell Pope. Many neo-classic architects, however, also worked in other styles on demand of the client. See FRENCH ART; FURNITURE. —L.D.L.

**Nergal.** *Babyl. relig.* God of the midsummer sun.

**nero-antico.** A black marble thought to have come from ancient Laconia; discovered among fragments of Roman ruins.

**NETHERLANDISH ART.** The geographical area defined by the term Netherlands (Lowlands, Low Countries) corresponds roughly to the territory now occupied by the Kingdom of Belgium and the Kingdom of the Netherlands (also called Holland), bounded by France in the South, by Germany in the East, and by the North Sea in the West and North. Originally a more or less unified area in all essential respects, the Netherlands were politically and art-historically divided into two sharply separated countries by the end of the 16th cent., when the great revolution resulted in the final independence of the predominantly Protestant and democratic northern (Dutch) provinces from the Catholic-monarchic southern part. In art history, the latter can be largely identified with its Flemish-speaking provinces since the artistic achievements of the Latin part of its population (the Walloons) were comparatively negligible after ca. 1300. Differences of style are noticeable before that final separation of North and South but they hardly justify any strict division. Even after that, the deep racial and cultural kinship of the Dutch and the Flemish peoples (which is evidenced by their common language) resulted in a great number of affinities in their art which may also warrant their being treated under the same heading. The salient facts of the history of the two territories must be assumed to be familiar to the reader of this brief survey.

*Middle Ages.* In the early and high Middle Ages, the Netherlands reflected the art-historical situation of the great neighboring countries in varying measure, at the same time adding to it a small number of important features, with the southern part by far predominating. In architecture, significant contributions to various phases of the Romanesque style were made (Nivelles, Tournai). Sculpture, particularly bronze and goldsmith work, came to the fore with Renier de Huy and a number of shrines of the 12th and 13th cents. Great losses among works of the mural painters have focussed our attention on excellent book illuminations of the Romanesque period.

Greater independence was secured with the coming of the later Gothic age. The rising power and wealth of the middle classes account for a remarkable predominance of civic over religious architecture; town halls and guild halls of the southern Netherlands are the most important examples of that exuberantly decorative branch of Gothic architecture. In sculpture, a powerful synthesis of monumentality and realism was achieved in the works of Claus Sluter (late 14th cent.) altho most of them were done in Burgundy, i.e., in the homeland of the new rulers of the Netherlands. In painting, the years around 1400 saw the leadership of the Netherlandish book illuminators quickly and firmly established although here, too, the development is inextricably connected with southern (Italian and French) sources and with the patronage of French and Burgundian princes (the Brothers Limburg, Jacquemart de Hesdin).

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

In these works, the innate tendency of Netherlandish art toward straightforward, uncompromising observation and rendering of daily life and its implements according to their individual texture and to their varying appearance under changing conditions of light and spatial setting, emerged as the main source of modern painting of the North. In contrast to Italian Renaissance painting of the same period, this new "realism" of the 15th cent. was not supported by scientific and theoretical endeavors but remained essentially a matter of empirical approach. The southern area, more wealthy and powerful than the northern, continued to lead the way although a considerable number of its main masters immigrated from the North( and also from the East). Altar painting became the most decisive task (Ghent altar-piece by the brothers van Eyck, 1432; Master of Flémalle, Rogier van der Weyden, Dirk Bouts, Hugo van der Goes, Hans Memling, Gerard David); portraiture made tremendous strides (same masters); other secular commissions increased. Book illumination continued important. Tapestries after designs of the great masters played a great role. What remains of the output of the northern provinces reveals a less homogeneous, highly individual production (Geertgen van Haarlem, Jerome Bosch). In the history of the graphic arts, Netherlandish engravings and woodcuts (particularly book illustration) hold a respectable place.

*Sixteenth Century.* Italian Renaissance principles proper were first introduced into Netherlandish painting by Quentin Massys whose role is comparable to Albrecht Dürer's in Germany, but much of the average production remained late-Gothic, often in indissoluble fusion with borrowings from the most recent Italian developments (Mannerism, q.v.). The tension resulting from the simultaneous influence of many Italian styles of the past and the present characterizes most of Netherlandish 16th cent. art. It took Netherlandish architecture a long time to go beyond casual assimilation of Italian Renaissance ornament and to penetrate to the principles of Renaissance architecture proper. Sculptors, too, combined northern tradition with Italian borrowings, the eventual result being something like an international mannerism after the middle of the cent. (Cornelis Floris). The development in painting was desultory. Specialization in various subjects started in the South although the North was eventually to profit most from it. Besides portraiture (Massys, Mor, and the beginnings of group portraiture in the North), landscape became one of the most prominent fields (Patenier, Pieter Brueghel the Elder). Every-day-life (*genre*) painting reached great heights (Massys, Brueghel). Mythological representations became more popular. Religious painting continued important (B. van Orley, Brueghel) but in a vastly more individual spirit, even where the task remained ecclesiastical. Panel painting reigned supreme; tapestry work was still outstanding while book illumination declined. Engravings played an ever greater part. The uprising of the Protestants against the Catholic Spanish government was marked by great destruction of religious works of art, particularly in the North (1566), and when the opposition in the southern provinces weakened (after 1580), the differentiation between Dutch and Flemish painting became more obvious. In the Protestant North, altar painting was reduced to a negligible role, making room for a democratic art still controlled by guilds but primarily aiming at the edification and aesthetic satisfaction of the people while the Catholic-monarchic South largely continued the tasks set by the Church and the princes though the importance of civic enterprise should not be underrated.

*Seventeenth Century.* Separation into Flemish and Dutch art becomes inevitable here, at least as far as painting is concerned. Flemish architecture was overwhelmingly influenced by Italian models of the specifically baroque type, with the Jesuits playing a great role in church building; naturally, civic architecture was more outstanding in Holland, with work in brick gaining (Hendrick de Keyser), and became decidedly classicistic around 1650 (Jacob van Campen). Sculpture remained essentially of an international type everywhere (A. Quellinus, R. Verhulst), with few works exceeding average quality.

True to the monarchic-Catholic character of the southern constitution, Flemish art of the 17th cent. was dominated by the Catholic diplomat Pieter Paul Rubens whose leadership was uncontested throughout his life. Excelling in nearly every branch of painting, including altar and mural painting, absorbing the best of Italian art of the Renaissance and of the beginning baroque in a thoroughly integrated and essentially original fashion, he presents the sum total of Flemish baroque art with that robust exuberance which characterizes the national spirit but at the same time, with an aristocratic restraint, a schol-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

arly cosmopolitanism, and, last but not least, in a synthesis of firm design and coloristic splendor entirely his own. His European reputation as well as his influence on European painting of all subsequent epochs, can hardly be overrated. Since his "best pupil", Anthony van Dyck, mainly a portraitist, lent the best efforts of his hypersensitive and elegant art to Italian and English sitters, Rubens dominated the scene in Flanders all the more effectively, and remarkable talents like Jacob Jordaens and Cornelis de Vos were hard put to it beside him. There was freer outlet for that genius of genre painting, Adriaen Brouwer, and his followers (D. Teniers), as well as for many specialists in landscape and still life painting who nevertheless did not achieve so great a distinction as did their Dutch contemporaries.

Compared with Flemish painting of the 17th cent., Dutch painting of the same period offers an infinitely more complex aspect, again in complete accordance with its different political and religious status. Our modern evaluation of a few Dutch artists (Rembrandt, Hals, Vermeer) as the greatest of their time, is a matter of historical perspective rather than of contemporary judgment. The immense variety of important artists, of distinctly differentiated art centers, and of subject matter, clearly reflects the democratic setup of the Protestant republic. The tasks of the painters were more numerous than elsewhere, calling for a host of specialists in each field. While Protestant religious painting was hardly popular enough to absorb the entire strength of any single artist, there were specialists in historical and mythological subjects, in landscape, seascape, animal, still life portrait, every-day-life, and architectural painting. There were even specialists in winter and moonlight landscapes, and specialists in painting *staffage* figures into other artists' landscapes. As to art centers, Amsterdam, Haarlem, Leiden, Delft, Utrecht vied with one another in richness and diversity of output. Mythological and historical painting found great encouragement from official sources and learned individuals, and was often desired for mural decorations (Amsterdam Town Hall). The main patronage in the other fields came from the public at large and concerned works to be hung on the walls of private homes, with the main exception of corporation portraits, a typical Dutch branch of painting fulfilling a democratic task par excellence. Undoubtedly, religious painting culminated in Rembrandt's non-sectarian profundity, with the Old Testament playing as great a role as might be expected from a representative of a nation which liked to parallel its own history to the history of the Jews, and from a man who lived in close contact with the Jewish community of Amsterdam. The beauty of their own country began to inspire Dutch landscape painters by the 2d decade of the cent. Their art passed through the diverse phases and trends of a more matter-of-fact (Jan van Goyen, Salomon van Ruysdael) and a more romantic interpretation (Rembrandt, A. Cuyp, Jacob van Ruisdael, Hobbema). After ca. 1645, interest centered more often on Italian scenery (Jan Both, N. Berchem). Portraiture ran the whole gamut between solid substantiality, the daring and often profound improvisations of Frans Hals, the great character studies of the mature Rembrandt, and the elegant flatteries of the *fin de siècle*. Genre subjects were sympathetically and simply viewed and either painstakingly or more broadly rendered by a host of great talents, with preference bestowed on the life of either the middle classes (Gerard Terborch, Vermeer van Delft, Pieter de Hooch), or of the lower classes (the brothers van Ostade), or of both, often with a touch of half mocking, half allegorical-moralistic goodnaturedness (Jan Steen). The outstanding names in seascape painting are Jan van de Cappelle and Willem van de Velde, in animal painting Paulus Potter, in architectural painting Pieter Saenredam and Emanuel de Witte. Only a word can be inserted on the formal problems and developments within this vast realm. The style of the most important masters is unmistakably Dutch, with comparatively few of the Italian reminiscences which were so characteristic of 16th cent. Netherlandish painting; it is sober without being trite or dry, usually less exuberant than the works of their Flemish contemporaries. Spatial freedom in indoor and outdoor scenes is a characteristic. The coloristic treatment varies from early multiplicity to monochrome tonality (most typical of the 2d quarter of the cent.) and to the use of Rembrandt's chiaroscuro or of more separate areas of contrasting colors (2d half), while the underlying design developed from corresponding multiplicity to greatly reduced and unified material and to a more restfully balanced composition with solid masses (most clearly noticeable in landscape painting).

Even the shortest account of Netherland-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

ish art of the 17th cent. must lay some emphasis on the line engravings and etchings produced at that time. Here again, Holland took the lead over Flanders where such contributions as van Dyck's *Iconography* (portraits of famous contemporaries) are rare. In the North, many landscapes (Hercules Seghers, Rembrandt, Ruisdael), as well as the religious works and the portraits by Rembrandt mark one of the greatest epochs in the history of etching. Among the works of the minor arts, Dutch ware (Delft) deserves especial praise.

*Eighteenth Century.* It has never been doubted that Netherlandish art suffered a wholesale decline during the 18th cent. The parallel to the political situation is again obvious. Imitation of foreign models became the rule rather than an exception. The classicistic theory and taste of the French artists of the court of Louis XIV had already made an inroad on late 17th cent. Netherlandish art (Gerard de Lairesse); it alternated with lame variations of the national heritage. This is true of architecture, sculpture, and painting, of the northern and the southern provinces alike; only a few genre painters (Cornelis Troost) and Dutch portraiture present a slightly more favorable aspect.

*Nineteenth Century.* Soon after the Napoleonic troubles, Belgium emerged as an independent nation (1830). Its architecture shares the defects characteristic of all European buildings of the time: eclecticism and bombast, until at its very end an important harbinger of new trends appeared in the person of Henri van de Velde. Sculpture produced nothing of outstanding merit until Constantin Meunier set the pace for greater sincerity in content and style. There was hardly more promise in painting until the advent of the painted and etched fantasies of James Ensor.

As to Holland, architecture and sculpture can be passed over in silence. But in painting, there was a more important movement which, though indebted to the national heritage of the 17th cent., produced works of unmistakable originality (Jan Bosboom, Josef Israels, the three brothers Maris). It should not be forgotten either that the art of Vincent van Gogh belongs to his homeland at least as much as it does to his adopted country France.

*Twentieth Century.* While the promising developments in Belgian architecture of the late 19th cent. bore fruit outside rather than inside the boundaries of their homeland, Dutch modern architecture found its fulfillment at home in addition to making important contributions the world over. In fact, Dutch architecture, particularly in brick, has become a driving force in contemporary building but has primarily made Holland herself a "good place to live in" (Berlage, de Bazel, Dudok). In sculpture and painting, neither Holland nor Belgium have as yet excelled. See FLEMISH ART. MOST IMPORTANT SOURCES: Carel van Mander, *Het Schilder Boeck,* first ed. 1604, best modern ed. by H. **NEW ATTITUDES FOR THE FUTURE OF ARCHITECTURE.** The cataclysmic world in which we live today is of particular significance and consequence to both educators and practitioners in the field of American architecture. American society will be considerably shaken by the impact of the world-wide shock of the war and will be affected accordingly. The post-war adjustments which will be necessary in America will create certain new social patterns which will be considerably different from those to which we have become accustomed in the past. The future of American architectural education and practice is clearly related to these new patterns; they are of serious import to every one now engaged in architecture.

It is the purpose of this article to review some of the important relationships existing between architectural education, professional practice and the broad needs of society, and also to suggest a program which can be established to better train and equip those engaged in architecture for the new problem of our post-war society. It is imperative that definite action be taken now toward such ends if architecture is to survive and remain under its present leadership.

The future of American architecture rests upon the shoulders of the men of vision in education and practice wherever they may be. Their prime responsibility is to endeavor to meet the problems with broad and intelligent planning and with the promptness the situation demands. Architecture has had a useful place and purpose in society through the ages and has contributed much to the well being of society. The future of architecture, under planning, is bright, it can again be the source of great good for mankind; but to be most useful in the future it must have new curricula, new professional viewpoints and above all else "new attitudes". These are the basic tools for approaching the important new opportunities which lie ahead in a better planned American society.

A brief examination of the present conditions and the trends for the future should convince the most obdurate, that their status as educators and practitioners has been fundamentally affected. New responsibilities will be imposed upon both these closely allied groups by society; and architecture's relationship to the whole pattern will be markedly different from that of the past. The architectural educator and the practitioner must

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

realize what the differences are, what the new responsibilities imply, and prepare those engaged in architecture to meet such obligations for the best interests of future American society and architecture.

These changes, because of their scope and nature, point toward a broad study, clear understanding, and use of the concepts underlying the social, economic, and political structure of our country. This changed direction in architectural thinking and practice is a new route to follow but it will lead to a sound basic premise for better and closer integration of the efforts of the architectural educator and the practitioner than has obtained in the past and an indispensable aid to solving their mutual problems for the future.

The ultimate objective of American architectural education has always been to train and equip the student with the knowledge and use of the essential tools required for a future professional place in architecture. Architectural curricula have always been planned for and were dependent on the broad needs of the architectural profession. Usually these curricula emphasized design and planning, and the problems of design and planning usually centered upon special types of buildings in limited fields. Varying lesser degrees of importance were given to the engineering and cultural subjects. Too often these collateral subjects were covered insufficiently, and they usually did not bear any particular relationship to the design and planning previously mentioned. One might charitably state that they satisfied the requirements for a college degree and the permission to apply for examination to the state board of registration three years after graduation. The far-reaching needs of society, if sketched at all, were only briefly presented through a study of the history of former civilizations. The study of modern society and its problems were not usually included. Consequently, the student's knowledge of architecture was specialized in design and planning. A broad knowledge of the problems of contemporary society was not obtainable in his college course, and unless he gleaned information from other sources he remained uninformed.

As the architectural curricula were dependent upon the broad needs of the architectural profession, likewise was the architectural profession dependent upon the broad needs of society. Unfortunately for architecture, society's needs were never clearly understood by the profession. The practitioner was himself a designer, planner and business man concerned primarily with highly specialized building types, and was not prepared for nor specially interested in the wider aspects of building for society. This attitude of the profession was naturally reflected in the curricula of the architectural schools.

The opportunities of the profession have not always been the same. They have varied considerably according to the stability or instability of the social, economic and political structure of the moment. Naturally when society was stable and prosperous the profession and the architectural schools were crowded with workers, at other times both groups suffered equally. Most of the hardships were caused by failure in the understanding of these social phenomena. The profession has always been unprepared to cope with change. Being technical specialists in mind and heart, with useful skills and knowledge of great merit and useful purpose, the profession has seemed content to rest upon such accomplishments and endure the periodic readjustments. That they were rather narrowly informed about the broad needs of society and what the true purposes of the profession were in relation to society seemed never to penetrate the profession's consciousness. Such a state of unpreparedness in the profession and lack of progressive educational curricula in architectural schools cannot again be tolerated for the future continuation of architecture in American society.

The United States has now entered another cycle of change which for severity, duration, scope and responsibility promises to be the greatest shock of all time to architectural education and practitioners. It is necessary that both groups understand the pending upheavals and plan for the essential adjustment, readjustment and reorientation of their course of action.

It will be necessary to prepare and equip those engaged in architecture to serve the larger needs of society first. The specialized skills which are already at hand can then be usefully employed to better advantage. The future of the architect calls for great collaboration with others in related fields. The degree of individualism which he enjoyed in the past is reduced, he will collaborate with the city planner, the engineer, landscape architect, lawyer, banker and many others. The future of architecture lies in the field of great public works of national, regional, state and city scope. Therefore the architect must prepare himself to fit into the technical groups

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

involved. He may be the coordinator, the leader, the planner or he may serve in some other capacity. This experience will be considerably different from that of the past, where he dealt only with the problems of the specific or single building type; there will be a splendid opportunity to concentrate on the planning of the group, neighborhood, city, region or state problems.

The architectural schools can contribute much to the understanding of social concepts, in fact some of the schools have already initiated programs in that direction and others are in the process of planning such curricula. Where such planning is not under way it should be begun at once. Most colleges and universities have departments of social, economic and political science. The faculties of those sciences should become a part and be integrated with the architectural curriculum. From the time the freshman enters the architectural school to his acceptance in the professional field, eight years have elapsed. Within that long period he should not be trained in the usual architectural skills alone, but he should also learn how society functions, how to plan for the changes, so that he may emerge a thoroughly trained unit to take his place in society.

The architectural schools in conjunction with social studies faculties could make immediate plans for classes in social planning for the architect now engaged in professional practice, to put him in closer touch with the changes which are taking place. It is almost imperative that this be the first step in the planning of architectural curricula, because the practitioner is immediately confronted with the problem of gainful employment and if properly informed would be immediately available and very valuable in the planning effort for early post-war activities now undergoing nation-wide study. All curricula for the architectural schools should be planned now for the broad training which its students will require when they return from their war service. Such planning for the future and preparation for the reorientation of the practicing architect would usefully employ the architectural and social studies faculties for a long time to come. Curricula for restoration of the practitioner need not be confined to architecture alone; why not include the engineer, lawyer, landscape architect, banker and realtor? All of these are closely related to architecture and society, but have seldom been brought together in a logically planned manner for a viewing of their interrelated and common problems.

The new curricula should include plans for non-professional education along similar lines. The public has always been slow to appreciate the services of the architect. There are some difficulties involved with the proposed new curricula, but they are not insurmountable. The faculties of our architectural schools must also realize that they must be trained in the broad concepts of society. They must quickly become informed and qualified to teach the subjects in relation to the architectural aspects of social problems. The task for the faculties to learn and to prepare for such teaching must be undertaken now if they are to make such courses available for the architects in time to be useful to them. The new curricula for the architectural schools should be prepared and ready when the students return from war.

Everyone concerned with the problems of architectural education and architectural practice must realize the tremendous advances and contributions which have already been made toward greater social security. The planning of the nation's resources are not temporary measures, and are on a scale never before attempted. Naturally they set the pattern for the future. They have laid new responsibilities on all of the professions, architecture must assume its share. The obvious course is to study the new patterns. The architectural schools must include these topics in their curricula, the architect must reorient his viewpoint; both must adopt "New attitudes". —R.A.F.

**New Negro Movement, the.** See AMERICAN NEGRO ART; AMERICAN NEGRO LITERATURE.

**new objectivity** (*Neue Sachlichkeit,* sometimes also called *Magischer Realismus,* magic realism). A phase of modern German art which (ca. 1922) follows Expressionism (q.v.). The term was introduced by G. F. Hartlaub in 1923 as the name of an exhibition which was planned for the fall of 1923, but which had to be postponed and which was held at the Mannheim *Kunsthalle* in 1925. The artists of the New Objectivity considered themselves in strong opposition to the Expressionists whose work they believed to be too fantastic and irrational. The New-Objectivists requested an "objective" (*sachlich*) approach to the world in which the modern artist lives. It has been said that New Objectivism is a reactionary movement going back to the depicting of natural forms. While it is obvious that Dix, Kanoldt, or Hofer go back to nature, it must be observed that their smooth, painstakingly accurate and carefully modelling technique is applied to a different concept of nature. Underneath the natural forms which Alexander Kanoldt selects for his still-lifes, the cacti, rubber trees, flower pots, etc., there seems to be discernible the basic geometric shapes of cube, cylinder, globe, etc., to which the plants, etc., are reducible (and in contrast to impressionistic painting the objects are not fused with the surrounding atmosphere). To a lesser degree this holds true for the art of Karl Hofer, who among the German artists comes perhaps closest to the work of Cézanne.

Georg Schrimpf builds up his figures in a manner similar to that of Kanoldt (e.g., *Sleeping Girls,* 1926), but in his later landscapes he modifies his objectivism in favour of simple lyrical qualities. Otto Dix and George Grosz use a painstakingly and sometimes almost microscopically correct technique to analyze and to depict mercilessly their human models (e.g., Dix, *The Artist's Parents,* 1921; Grosz, *Portrait Dr. Neisse,* 1927) or they show with brutal frankness the horrors of war (Dix) or the wrongs of society (Grosz). Max Beckmann's work shows a change from heavy plastic and often fantastic compositions (e.g., *Balloon Acrobats,* 1925) to a style of painting more colorful and lighter in the treatment of forms (e.g., *Quappi,* 1937).

In architecture, design of furniture, etc., the New Objectivism emphasized simplicity of line and the function of useful objects as the all-important criteria. See GERMAN ART; also *Modern German Painting and Sculpture,* Museum of Modern Art, New York, 1931; F. Roh, *Nachepressionismus,* 1925; B. Taut, *Die neue Wohnung,* 1928, 5th ed.; F. **nimbus.** *A. Circular nimbus or Halo*: A symbol of light and glory, surrounding the head. The term *nimbus* in the meaning of a cloud of light first occurs in Virgil, but the idea is at least as old as Homer. In classical art the nimbus and more rarely the aureole (q.v.) were sometimes attributed to divine or deified persons, particularly in paintings. Divinities connected with light, such as Helios, etc., were given the nimbus more often than others, but there was no strict rule. The oldest certain examples of round nimbi are to be found in the paintings of Apulian vases of the 4th cent. B.C. There they usually consist of several concentric rings of light, with rays radiating from the periphery. Kindred attributes were circles of rays or diadems or crowns with rays. The nimbus as a simple disk first occurs in the frescoes of Pompeii; various light colors, not yellow or white only, are used, which makes it clear that it is not the sun or moon that are represented, but rather an aura of light which has its source in the person whose heads its surrounds. Now it can be observed that the Roman painters gave nimbi esp. to those figures of gods or heroes who have an artistically prominent role in the composition of the pictures. It seems therefore possible that the original form of the halo as a

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

"cloud" of light, consisting of different spheres and ending in rays, was transformed into its later disk-like shape under the influence of the *clipeus* (q.v.) or round shield which was the characteristic background used by the Romans for the portraits, in color or relief, of famous men and later of ancestors, heroes and emperors, and which by the early Christians was transferred to Christ and his saints, like the nimbus itself.

The hypothesis which would derive the nimbus from circular rings around the heads of statues, meant to protect them from birds and from damage in general, need no longer be taken seriously.

In Christian art, from the 2d quarter of the 4th cent. onward, the circular nimbus was given to Christ, the Lamb of God and the Phoenix (symbol of resurrection). From the 5th cent. it was given also to angels, apostles and saints and to the Virgin. The nimbus of Christ was soon differentiated from the other nimbi, by placing a cross on the nimbus itself. From the 5th and regularly from the 6th cent. the nimbus with inscribed cross, the so-called **cross-nimbus**, became *the* attribute of Christ in art.

A short time before the adoption of the circular nimbus into Christian art it had become an attribute of the Roman emperors, and as such it appears occasionally in the 3d cent., regularly from the time of Constantine the Great. It was from the imperial images, not from the pagan gods, that the nimbus was transferred to Christ as the highest ruler. Biblical passages about the supranatural splendour of the face and head of Christ or God may however have contributed to the adoption of the nimbus by the Christians. In the Byzantine sphere of influence the nimbus remained an attribute not only of Christ and the saints, but also of emperors, and occasionally of other important persons as well as of allegorical and mythological figures.

The oldest nimbi in Indian and Iranian art are comparatively late; see for instance the nimbi of Indo-Bactrian Kings of the 1st cent. B.C.. in their coins, the nimbed Buddhas of Gandhara art, and some figures in Seleucid-Parthian and in Sassanian stone reliefs. It is therefore scarcely possible to adopt the idea that the Greco-Roman or the Christian nimbus originated in India or Persia. For later examples of Persian and Indian nimbi and aureoles and their possible relation to Iranian and Indian light-worship see Ramsden, Coomaraswamy and Travenor-Perry.

*B. Square Nimbus*: This attribute, much more limited in scope and much rarer than the halo, is no nimbus in the proper sense of the word, as it has nothing to do with the symbolism of light. In the older examples it is either a square or rectangular full surface of blue or greenish-blue color or a dark-colored frame-line of approximately square shape. While in classical and in late-medieval and modern art the position of the round nimbus is not unfrequently adapted to that of the head, the square nimbus (like the polygonal one) always remains parallel to the background. There are no surviving examples of square nimbi in sculpture (it should however be observed that in the case of the circular nimbus it has been proved by Krücke [*Zeitschrift fur neutestamentliche Wissenschaft*] that the latter was sometimes painted on the background of reliefs).

There are two principal regions and periods in which the square nimbus occurs: (a) Rome and Monte Cassino, whence it spread to various parts of the Christian west. Its first certain appearance in this zone is around 700 A.D.; after the 13th cent. it is no longer in use. (b) Christian Egypt, where it is found in Coptic frescoes of the 6th cent. (Bawit, Saqqara). There is, however, the strong possibility of an earlier occurrence in the catacomb of Karmouz near Alexandria, in a fresco probably dating from the 3d century. This case would not be unique, as there is at least one certain instance of the square nimbus in the 3d century Synagogue frescoes of Dura-Europos on the Euphrates, where it surrounds the head of the white-haired man, to the left of the central panel on the west wall, who probably is Moses or Abraham; Alexandrian Judaism might form the link between Egypt and Dura. A late Coptic example of the square nimbus, probably dating from the 12th cent., is to be found in *Deyr Ambâ Hadra* ("St. Simeon") near Assuan.

The square nimbi of group (a) were used to distinguish contemporary, saintly and important persons, such as Popes, founders of churches, etc.; after the 9th cent. this meaning of the square nimbus was no longer always understood. The square nimbi of group (b) had their origin in rectangular set-offs of the portraits on late-antique mummy-shrouds. By at least about 200 A. D. these set-offs seem to have been connected with symbolical ideas concerning the perfection

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

of the square and rectangle. Thus the square nimbi of Coptic art and perhaps also of early medieval Roman art were symbols of perfection. The diffusion of the symbol from Egypt to Rome occurred during a period of strong oriental influence in papal Rome. Concerning the allegedly earliest occurrence of square nimbi in Rome during the pontificates of Gregory the Great (590-604) or even Liberius (352-66) see my above mentioned article, where the untenable hypothesis that the Roman square nimbi originally were imitations of portrait-panels or super-imposed layers of stucco in fresco-portraits, is likewise discussed.

*C. Polygonal Nimbi*: Lozenge-shaped and hexagonal nimbi appear from the end of the 13th cent. onward, esp. in Italian painting, (but see also the reliefs of the virtues on Andrea Pisano's bronze door of the Baptistery of Florence). These nimbi are symbols of light, painted in gold like the round haloes. They are usually given either to allegorical figures such as the Franciscan virtues on the vaults of the lower church of S. Francesco at Assisi, or to persons of the Old Testament. But sometimes Christ Himself or, more frequently, God the Father has a lozenge-shaped nimbus (see for instance God the Father in Raphael's *Disputà*). Beside the lozenge-shaped and hexagonal nimbi, regarding the symbolism of which some suggestions are advanced in my article on the square nimbus, there exist also some examples of octagonal nimbi in Catalonian paintings of the 15th cent., in which some Old Testament figures are thus shown. **non-conforming use.** See CIVIC PLANNING.

**non-objective painting** (Fr. *non-figuratif*). The term "non-objective" is supposed to have been used for the first time by the Russian Alexander Rodchenko. Kasimir Malevich, another Russian, is said to have been the first to concentrate on entirely abstract, non-objective paintings (which he called suprematist) in 1913. Non-objectivity, young as it is, may easily change its name before it will have its ultimate denomination, yet for the time being the term "non-objective" has been rather generally accepted, even while many artists are opposed to a non-name which they do not consider constructive enough. Yet more significant than its name is the complete reversal of its philosophy of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

art in comparison to the older forms, surrealism included. Its basis is the utmost purity of pictorial means inasmuch as it wants to give a work built up entirely on its own merits and laws, to be a unique creation in its own space, not intellectually associable to anything else in the world. The non-objectivist uses his medium, line and color, not to portray any happening, historical scene, still-life, portrait or anything else, but, like the composer, to create freely following his intuition without introducing light and shadow, perspective, texture, psychological features or resemblance. Up till now three different styles can be distinguished: a free style, sample of which is Kandinsky's *The White Edge* (1913), a strongly architectural style, like Bauer's *The Holy One* (having inspired the theme center of the New York World's Fair, 1939) and very recently a lyrical style, developed also by Bauer, a sample of which is *Spirituality* (1938).

The non-objective creation can only be viewed in its oneness and is not to be compared to any other creation; it can only be taken as a work whose intentions are harmony, beauty and order. It is self-evident that the education of our eye through the centuries does not allow us to jump from our most materialistic level to non-objectivity in a day. The patient onlooker will discover how, slowly, he will derive more and more pleasure from the consummation of non-objective work and he will feel his soul getting the wave-length of it more and more, until it finally swings in the same accord.

Most of the members of the American Abstract Artists have progressed from abstraction to non-objectivity. The industrialist Solomon R. Guggenheim has endowed a Foundation of Non-objective Art in New York, incorporated under New York State laws on June 25, 1937, and has opened a museum at 24 East 54th Street in New York City devoted exclusively to the exhibition of non-objective art.

A large number of works at the Gallery of Living Art (New York University) is non-objective.

The most outstanding masters of non-objective painting are Wassily Kandinsky, who started to work "concrete" in 1911, and Rudolf Bauer, living in the U. S. A. since 1939. Other important non-objectivists are: Otto Nebel, Ladislaus Moholy-Nagy (Director of the School of Design, Chicago), Charles G. Schwab, Fernand Leger, Jean Xceron and Penrose Centurian. **non-strophic song.** See song.

**nook.** A recess, as in a wall.

**Nordic style.** Term used to describe the art of Teutonic, Celtic, Anglo-Saxon and other Northern barbaric peoples of the Middle Ages, characterized in style by a dynamic, linear expressionism often suggesting a chained or suppressed psychic energy, and in subject matter by a preference for animal motives. It contrasts stylistically with Latin illusionism (q.v.) and with Byzantine symmetrical design, balance, proportion, and restraint. One may cite as examples Celtic and Anglo-Irish illuminated manuscripts from the 8th to 12th cent., some French Carolingian illumination (e.g., School of Rheims), and much German Carolingian and Ottonian art.

In the broad sense the term "Nordic" may be used to describe that art of the Romanesque, Gothic, and Renaissance periods in Northern countries, in which the barbaric, dynamic, psychically-energized style dominates in the fusion with illusionism and Byzantine design, which takes place in Northern European art from the Romanesque period on. Thus, German Gothic architecture, sculpture, and painting are dominantly "Nordic", as are Dürer, Grünewald, and Altdorfer in German Renaissance painting. The term is synonymous with the original meaning of the word "Gothic", as referring to the barbarians of the North rather than as the designation of a historical period; and though the word "Gothic" did not originally have a connotation so precise as "Nordic" has today, the two words are now often used interchangeably.

In Nazi Germany the term "Nordic" has been misused in art to describe 19th cent. international naturalism and popular romanticism (qq.v.), which the Nazis erroneously consider the native idiom or racial style of their local ancestors. —L.D.L.

**Northwest Coast Indian art.** The Northwest Coast Indians occupy the rugged, heavily timbered coastal fringe of British Columbia and southeastern Alaska. The chief tribes are the Nootka, Kwakiutl, Bella Coola, Haida, and Tsimshian in Canada, and the Tlingit and part of the Haida in Alaska. Little is known of the prehistoric era, but much may be inferred from the rich, spectacular culture attained in the 19th cent., largely through the acquisition of metal tools from the white man. The use of the new tools seems not so much to have changed the pattern of the culture as to have broadened its scope and improved its quality. On this coast nature is prolific for a hunting and fishing people. Game, plentiful on land and sea, and timber from the heavy forests of red cedar that cover the mountains, provided the materials for food, clothing, houses, and all the needs of daily and ceremonial life. Social patterns, which involved heraldic display of prestige and wealth, religious, especially Totemic, beliefs, and a vast store of legends were basic in their art expression. Thus it emphasized representation, though in highly conventionalized form, and at the same time subjected the content rigidly to the requirements of organization within a space. In design the curved line is predominant except where the medium demands angularity, as in basketry.

The woodcarving of these Northwest tribes was not only their most important art but one of the highest manifestatoins of the craft in the Americas. In neolithic times, that is, before the first appearance of the white man in 1774 A.D., stone sculpture, carved with stone tools, massive and conventional representations of totemic animals, served as a prelude to the great florescence following on the introduction of steel tools, which enabled the artist to make freer use of his abundant timber: houses with carved ports, totem poles (q.v.), carved canoes, chests, food dishes and innumerable other articles of daily living, and masks for ceremonial purposes. The style varied somewhat among the tribes; it was weaker in the south, reached a climax of power among the Haida, and gradually merged in the north into the walrus carvings of the Eskimo. Still, it had some common characteristics. Its content derives partly from man and partly from native creatures—the killer whale and shark, the beaver, bear, wolf and frog, the raven, hawk and eagle. While some of the human figures approach naturalism, the animals and birds are represented in a unique convention that has nothing to do with the illusion of natural appearance. On the contrary, the intention is to lay out on a surface all the parts of the creature, some seen in front view and some in profile, and at the same time to organize these parts into the space to be filled. To differentiate the parts, carvings are painted and sometimes inlaid with abalone shell. Masks for purposes of ritual and entertainment and for the dramatization of legends reached a high level of imaginative power and were ingeniously contrived so that beak, eyelids and jaw were movable and could be manipulated by strings so as to create varying effects.

Another material used with skill was the horn from mountain goats and sheep, which was softened, moulded into dishes and ladles, and carved and engraved in the same general style seen in wood carving, with, however, due regard to the difference of material.

Painting served the same function as carving—to display ancestry and illustrate legends for a people with no system of writing, and to decorate; and it followed the same general style except for a greater fluidity in execution due to the medium. The rectangular wooden houses with low, sloping roofs and few openings offered large areas for painting, both outside and inside. These paintings, when on the façade of the house, together with the carved and painted totem poles set up in front, doubly emblazoned the social rank of the owner. In like manner the sides of the great canoes were carved or painted with totemic emblems.

Since no pottery was made, baskets were important as containers. They were made entirely by the women, of roots, grasses and stems, by a tight twining technique. They are cylindrical in shape and are decorated with bands of geometric patterns made of colored grasses used not structurally in the twining but like embroidery or brocading.

Another craft of the women was weaving, though on designs furnished by the men. Notable are the long fringed blankets of the Chilkat, a subdivision of the Tlingit. They

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

were worn like capes in a ceremonial costume which included, in the case of a chief, an elaborate headdress of carved wood decorated with shell and ermine, and painted leather kilt and leggings to which were affixed bits of bone and ivory that would clink with each movement. The blankets were woven of wool and cedar bark on a loom with an upper beam only and hence a loose warp. The designs, in black, white, yellow and green, show the same kind of conventionalization as that found in the carvings and paintings. See Franz Boas, *Primitive Art,* 1927; Frederic H. **note.** An artist's rough sketch, esp. of a detail.

**NOVEL, THE.** The long fictional prose narrative called the novel had forerunners in antiquity, and in the **medieval romance** of chivalry telling of knights encountering giants and monsters for love of fair ladies; in the pastoral romances of the Italian Renaissance, about shepherd's and shepherdesses in artificial outdoor scenes; and in the **picaresque stories** of the Spanish Renaissance, stringing together the escapades of rogues. The first great example of the modern novel is *Gargantua and Pantagruel* by Rabelais (1495-1553), abounding with the new surge of life and learning in a rebirth of language, and delighting in full-bodied facts of human nature. The second is *Don Quixote* by Cervantes (1547-1616). It achieved, also in gloriously adequate language, an interaction between the idealism attributed to shining knights and the realism of common men, transcending the cynicism of the picaresque attack upon anachronistic and exaggerated ideals, to arrive at a humorous and tragic sense of man trying to rise while keeping his feet on the ground. The subsequent course of the serious novel is an attempt at adjustment between fact and aspiration.

In 17th cent. France the burlesque genre represented by the *Roman Comique* of Scarron (1610-60) is important as an ancestor of realism. Of lasting interest is *La Princesse de Clèves* by Mme. de La Fayette (1634-93), from which the current of psychological fiction leads to *La Chartreuse de Parme* and *Le Rouge et le Noir* by Stendhal (1783-1842), and to Proust and Gide in our time. In 17th cent. England the gravity and excitement of events and the feeling that familiar things were charged with inner meaning, was expressed in the realistic and allegorical story of *Pilgrim's Progress* by John Bunyan (1628-88). Defoe (1659-1731) continued the effort to produce fiction which should enhance life without seeming to deviate from fact, using the sober tone of journalism and the personal note of the diary. Dropping allegory he emancipated his sense of the marvelous from the medieval background and exercised fondness for picaresque event in terms of the contemporary world, as in *Moll Flanders.* In *Robinson Crusoe* he celebrated the resourcefulness of man overcoming nature and making himself at home in it.

This self-reliance, which fostered voyages of discovery and scientific invention, brought about the rise of the middle class. Recognition of this class was carried further by Richardson (1689-1761) in *Clarissa Harlowe,* depicting domestic life and manners, with a sentimental version of bourgeois values put forward in sheer moral purpose. Like Defoe, Richardson gained the illusion of intimacy through adoption of the diary style and maintained this effect, while shifting the point of view, by the device of imaginary letters. The introspective life of the sensitive person enabled and obliged by modern conditions to be self-sufficient, alone in the civilized world,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

alone even in the bosom of the family, as drawn by Richardson, was the counterpart of Robinson Crusoe who was alone in nature. Robinson is a symbol of competent problem-solving enterprise, whether scientific or commercial. Clarissa symbolizes subjective isolation in the transition from the transcendent values of the medieval communal world to the self-centered Renaissance and Enlightenment. Absorbed as Richardson was in the life of feeling, he maintained logical sequence. But Sterne (1713-68), though his work was careful, flouted the conventions of order in art and life to give the freest expression of his private self. Fielding (1707-54) allowed individual feeling to be inferred, yet did not shrink within it like Sterne, nor try to uphold inherited morality by urging personal holiness like Richardson, but attacked the brutality of capitalism in objective and realistic presentation of character. Fielding also advanced the technique of the novel by abandoning the single-file events of the picaresque story for the complex structure of simultaneous progression on several fronts toward controlled results.

Novels in the 2d half of the 18th cent. in France and England were sentimentally romantic and artificial, and scarcely deserve aesthetic consideration for themselves. Their importance consists in being part of the reaction against the spreading view of the Newtonian world machine and the rationalism or empiricism which denied value to the yearnings of the individual. A curiosity of the period is the Gothic novel, such as *The Castle of Otranto* by Horace Walpole (1717-97), which accompanied the sentimental attempt in poetry and architecture to escape from a sober present into a make-believe medievalism. The same escape-motive explains the 18th cent. love of Oriental fiction and imitations of it. In Rousseau (1712-78) this romantic mood turned to idealization of nature and protest against the artificiality of contemporary life. He expressed the worsening of social conditions through technological and economic changes characterizing the development of capitalism, as well as through the inertia of anarchronistic institutions and authority. Novels like his *Nouvelle Héloïse* and *Émile* are called "novels of feeling" or "novels of purpose" according as they stress sensibility or the need of reform, and they have special interest in view of his role as philosopher of the French Revolution. The novels of George Sand (1803-76) are comparable in their sentimental and social cast.

The German novel first attracted attention outside Germany during the latter half of the 18th cent. through *The Sorrows of Young Werther* (1774), Goethe's romantic epistolary novel written under the influence of Richardson and the German "Storm and Stress"; through Goethe's more earthly *Wilhelm Meister's Apprenticeship* (1796), and his problem-novel on marital relations, *Elective Affinities* (1809). In the same age Jean Paul Friedrich Richter wrote his whimsical, formless, dreamy novels of life in the land of "poets and thinkers" in the manner of Sterne (*Titan, Years of Indiscretion*), and members of the "Romantic School" published a number of "novels of education" (*Bildungsromane*) patterned on *Wilhelm Meister* but with less realistic power (Tieck's *Franz Sternbald's Wanderings,* F. Schlegel's *Lucinde,* Novalis's *Henry of Ofterdingen*). This type, philosophical, often autobiographic and little concerned with the contemporary scene but more with the individual, is the most characteristic type from Germany. In its attempt to depict the gradual maturation of a hero it may be traced to Grimmelshausen's *Simplicissimus* (1668) as well as to Goethe. The age of realism after 1830 witnessed its rapid development (Gottfried Keller's *Green Henry* and Eduard Mörike's *Painter Nolten*). We meet it also in our own age (Wassermann's *The World's Illusion* and Mann's *Magic Mountain*). The historical novel was cultivated by Wilibald Alexis (pseud. for Wilhelm Häring) early in the 19th cent., while between 1850 and 1880 Gustav Freytag and Theodor Fontane evolved a more realistic type concerned with men confronted by the social problems of their day. After 1885 the Naturalists, headed by Hauptmann, introduced the recent French and Russian novelists, while in the early 20th cent. Schnitzler, Kolbenheyer, Ponten, Carossa and many others have contributed novels which again reveal the typical characteristics of the German genre—less interest in action and plot than in character and discursive concern for philosophical and politico-social problems.

One may say that the failure of the French Revolution warped the novel throughout Europe in the 19th cent., as in Foscolo's *Le Ultime Lettere di Jacopo Ortis* (1802), an expression of Italy's disillusion. The virtue of the novel in the 17th and early 18th cents. had been full revelation of human nature, in its actual condition and in its ideal. But 19th cent. novelists seem to have been unable

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

or afraid to see man as he was, hence inadequate to his fundamental aspiration. Obliged to write for the bourgeoisie, if not actually in sympathy with it, they sensed that it could not solve its problems without a reconstruction of society as a whole, and that the middle class did not want to risk bringing back the Terror. So the age and its novelists hugged institutions antedating the French Revolution, and tended to keep within the shelter of gentility. Jane Austen (1775-1817), on the threshold of the period, limited herself to the local gentry, showing their foibles but not their setting. Scott (1771-1832), at a loss to handle the contemporary self in its own terms, disguised it in medieval trappings and removed it to a romanticized past. Following his lead the historical novel was carried on by Hugo (1802-85) and Dumas (1803-70) in France, Manzoni (1785-1873) in Italy, and Cooper (1789-1851) in the U. S. A.

The somberness of Hawthorne (1804-64) in *The Scarlet Letter* and the symbolistic pessimism of Melville (1819-91) in *Moby Dick* seem related to the romantic melancholy in Europe after the breakdown of the French Revolution and the disillusioning effect of natural science. Melville's very care with facts and figures pointed his determination to penetrate beyond them. Less devastating was the genteel realism of Wm. Dean Howells (1837-1920) in *The Rise of Silas Lapham.* Mark Twain (1835-1910) had a hatred of evil that went with deep love and knowledge of his country and people, but was mostly kept within the bounds of polite restrictions he could not surmount. That sex had no place in *Huckleberry Finn* is indicative.

Even Dickens (1812-70) did not attack the social system in general but particular evils, such as Yorkshire schools in *Nicholas Nickleby* and Chancery Court in *Bleak House.* Where he arrived at indictment it could pass for caricature and was blurred by sentimentality. It is unlikely, however, that he restrained himself. Perhaps he was not more critical of society because the richness of character, the kindness, sadness, folly, horror, and comedy of *Oliver Twist* and *David Copperfield* seemed too fundamental to be altered much by any reform or revolution. Thackeray (1811-63) satirized society in *Vanity Fair,* but within family relations rather than in larger aspects, approving conventional virtues which involved accepting the general scheme of things. Trollope (1815-82) in his methodical chronicling of respectability must have reassured his readers that all was well with their world. How life and love were stifled beneath that smugness one may feel in the outcry of *Wuthering Heights* by Emily Brontë (1818-48). George Eliot (1819-80) exalted the Victorian code in her novels. Meredith (1828-1909) had the comic sense to ventilate the stuffiness of his time, as in *The Egoist,* and accepted the theory of evolution. But he considered it to mean an unfolding plan culminating in intelligence and justifying optimism, hence underestimated the struggle ahead. Hardy (1840-1928) found the world indifferent to man in *Jude the Obscure* and interpreted the philosophy of science as blighting human prospects. Samuel Butler (1835-1902) in *The Way of All Flesh* held that character is molded by heredity and environment and cynically showed the importance of money to the well-being of his hero.

Henry James (1843-1916) was one of the first writers who strove consciously to make the novel a form of art in the fullest aesthetic sense. In Paris he was in contact with Flaubert (1821-80), Turgenev (1818-83), and the Goncourt brothers (1822-96, 1833-78), who were associated with the art for art's sake movement, of which Poe (1809-49) is considered to have been the prophet through his influence on the poet Baudelaire (1821-67). This movement opposed the apparent vitiation of art by the results of science and commercialism in modern life. Yet the naturalist Zola (1840-1902) was in the circle James met in Paris, and they all inherited much of the passion of Balzac (1799-1858) for observation and documentation, as did Maupassant (1850-93). French influence in the direction of naturalism and realism was also strong upon Italian writers in the second half of the 19th cent., such as Verga, Capuana, and Matilde Serao. *Il Santo* (1906) by Fogazzaro marks a new lease of life in the 20th cent. in treating the attempt to reconcile the value of religion with full recognition of science. *Il Fuoco* by D'Annunzio, on the other hand, shows reversion to art for art's sake, and a hardness toward the ordinary concerns of humanity consonant with fascism. The Italian novelist now best known is the anti-fascist Silone whose *Bread and Wine* compares socialism and Christianity in terms of deep sympathy with the people on the soil.

It is increasingly seen that, while the novelist must be an artist, life is the stuff of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

his art. This was the dual position of James and Flaubert as they analyzed and formulated the technical aspects of the once unpremeditated craft of fiction: James in his *Prefaces* and Flaubert in his *Correspondance.* Their ideal was a self-contained story, objective, free of essays or asides by the author except for good reason; and a unified point of view not allowed to shift unless for a justifying effect. Pictorial or panoramic passages were to be used for preparation, information, description and generalization; scenic or dramatic passages of dialogue and action were to put the high points before the reader. Since non-dramatic parts are likely to drag, it was felt important to heighten their interest by various devices.

Stevenson (1850-94), who had considerable correspondence with James, followed him in striving for form in the novel, but diverged from him in love of overt action and in emulation of the romancing Scott and Dumas. Stevenson's cultivation of escape retained much realism, and the same was true of Hudson (1841-1922). Since Hudson was at home in South America his fancy in *Green Mansions* was scarcely more romantic to readers of English than his nature lore. Kipling (1865-1936) also practiced ground-gripping romanticism, having the advantage of familiarity with India and animal life. But romance for him did not imply disapproval of the social order, as for Stevenson and Hudson. Kipling was eloquent in apology for imperialism.

To many readers concern for form and technique, or for anything less than the problem of fundamental values, began to seem as unimportant in the second decade of the 20th cent. as to the great Russian novelists then becoming familiar in English. Turgenev (1818-1883) was a consummate artist but concentrated his art upon the goal of relieving unnecessary suffering. He expressed Russia's need of reform in keeping with Western science and ideals, though he saw (*Fathers and Sons*) that the nihilist moved too destructively in that direction. Dostoievski (1822-81), concentrating upon the soul-searching of drab persons, condemned critical liberalism as well as headlong nihilism, believing that redemption for Russia lay entirely in Christian faith and love. He came to feel that this involved submission to traditional orthodoxy and authority. Tolstoy (1828-1910) gradually understood Christian brotherhood to dissolve orthodoxy, authority, nationalism, and all institutional structure which might oppress or exploit simple men, and was well on the way to this view in *War and Peace* and *Anna Karenina.*

Even Henry James and Flaubert, the technicians of fiction, are now appreciated for their social insight: for expressing the predicament of anyone sensitive to intellectual and emotional conflict in a culture perpetuating traditions and institutions incompatible with the advance of science and the rising demand for fairness to common humanity. *The Bostonians* and *The Princess Casamassima* by James, *L'Éducation Sentimentale* and *Madame Bovary* by Flaubert, considered as social philosophy have the limitations of their authors' education and experience. But it is largely owing to these men that critics now require adequate treatment of themes important to mature people, as well as formal excellence in presentation of character, in novels to be regarded as serious works of art.

In both requirements Galsworthy (1867-1933) ranks high. Yet, despite his social conscience, his imagination was so confined to the values of the middle class that, in presenting its decline in *The Forsyte Saga,* he seemed to be recording the downfall of the human race. Bennett (1867-1931) was a craftsman, though inartistic in sacrificing subtlety to thoroughness of documentation. He saw the writing on the wall for Victorian values, but did not seem to care as long as he could do a good job of reporting. Wells (1866) began writing fantastic romances based on the wonders of science, and went on to use the novel as the means of showing how adoption of scientific attitude and method was the best way of dealing with questions of sex, education, religion, and all the major difficulties besetting society. Taken to task by Henry James for slighting character analysis and the refinements of verbal texture in so-called problem novels, Wells replied, as in his *Experiment in Autobiography,* that he wanted to make the novel have effect on conduct. Feeling that the 19th cent. novel sinned by inculcating a false sense of security in the reader, he has believed the novel should give notice of general breakdown and the need of wholesale reconstruction on the basis of science. He has not seen how social purpose could be combined with the aesthetic ideal of James. Many novelists have sided with Wells in this controversy. If fewer have followed James, they have not been impressed by the numbers against them. Conrad (1857-1924) accepted

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

with reverence the Jamesian teaching and example, dedicating himself to the novel as a self-contained form of art. He too was impressed by science, but instead of seeing hope in it for the solution of basic problems he was like Hardy in thinking science required a mechanistic view devoid of hope. Conrad was consoled, or solemnly diverted, by the spectacle of man struggling to do his duty, especially psychologically, against a grand background of nature. He was disillusioned about man's fate, yet filled with romantic admiration for defiance of it. He felt that if one had the courage to overcome fear, death would lose its sting, as in the story of *Lord Jim*.

In modern Spain social considerations have largely absorbed the novel, and have drawn the American Hemingway to write a novel about that divided country (*For Whom the Bell Tolls*), as well as the Frenchman Malraux (*Man's Hope*). Unamuno, the dean of Spanish letters until his death in the civil war, though in the end tragically disappointed by the effort to block the forward-looking hope of his people, had sought in the past for fundamental Spanish traits, in *Paz en la guerra* (1897) and *Niebla* (1914). Pío Baroja, however, tore tradition for the sake of a dynamic concept of life in his trilogy *La lucha por la vida* (1904) and in *El árbol de la ciencia* (1911). Valle Inclán, though a modernist at heart, recreated a barbaric and legendary atmosphere in his kaleidoscopic novel of Latin American tyranny, *Tirano Banderas* (1926). Ramón Pérez de Ayala has unveiled human passions with Freudian curiosity in *Troteras y danzaderas* (1913) and has shown his intellectual and aesthetic preoccupations in *Tigre Juan* (1926).

In Latin America the Chilean Eduardo Barrios has delved into the complexities of human motives in *Un perdido* (1917) and *El hermano asno* (1922), while Mariano Azuelo has impassively viewed the Mexican underdogs swept by the revolution of 1910 in *Los de abajo*. The struggle between man and monstrous tropical nature is depicted by José E. Rivera in *La vorágine*, a story of the plains and jungles of Colombia. Rómulo Gallegos of Venezuela, apostle of progress, has expressed a more hopeful view of this struggle in *Doña Bárbara* (1929); and there is a similar confrontation of man and nature in *Don Segundo Sombra* (1926) by Ricardo Güiraldes of Argentina, a poematic novel of the pampas and the gaucho.

At its best the novel everywhere has continued to express the human situation colored by imagination, with the growing skill of reflection upon experiments in technique, and the intensified quality of life in crisis. The novelist of the 20th cent. has been concerned with the impact of science and technology upon inherited institutions and habits. Joyce of Ireland (*A Portrait of the Artist as a Young Man, Ulysses, Finnegans Wake*) with all the resources of language and great technical inventiveness, tried in vain to make his art replace the religion discredited for him by science. Proust of France (*Remembrance of Things Past*) strove to preserve personal reminiscence and traditional culture from science, and succeeded in recording the decay of the civilization he cherished. Thomas Mann of Germany has worked out a dialectical mediation between cultural conservatism and scientific progress (*Buddenbrooks, The Magic Mountain,* the *Joseph* series). Kafka of Czechoslovakia (*The Trial, The Castle*) has expressed the confusion of modern life and a hunger for a faith like that of Protestant orthodoxy while finding it no longer accessible. Aldous Huxley of England, after blaming a travesty of science for the degradation of life (*Brave New World*), has turned to quietism. D. H. Lawrence of England tried to find salvation in sex (*Lady Chatterley's Lover*). The loneliness of a sensitive woman who cannot grasp or accept the contemporary world except as she can dissolve it into subjective insights, is manifest in Dorothy Richardson (*Pointed Roofs*) and Virginia Woolf (*To the Lighthouse*), both of England. Malraux of France (*Man's Fate, Man's Hope*) calls for collective action against social injustice. Mauriac (*Le Noeud de Vipères*) and Bernanos (*Diary of a Country Priest, Star of Satan*), both of France, deal in Catholic terms with the struggle between good and evil. Roger Martin du Gard (*Les Thibault*) and Jules Romains (*Men of Good Will*), also both of France, survey extensively the topics of contemporary experience. Santayana of Spain (*The Last Puritan*) ridicules the effort to be virtuous and rational in what seems to him an absurd world. Gide of France (*The Counterfeiters*) indicates that absurdity and futility may be dissipated when men proceed in the adventurous experimental fashion that transcends preconceived goals. Apparently it is because American novelists have failed to grasp Gide's essentially American point of view that they have lately been very disillusioned. But they have been welcome to people who feel the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

need of a new realism about the state of things, as the first condition of any fundamental improvement. Sinclair Lewis (*Main Street, Babbitt*) has handled the American scene without gloves, and indicated (*Arrowsmith*) that science, the hope of our time, tends to be corrupted by commercialism. Dreiser (*An American Tragedy*) conveys the sense that social changes accelerated by science and industry, as vitiated by capitalism, have badly damaged traditional values. Hemingway in his fashion has illustrated their depreciation, and has tried to start from scratch toward rebuilding them (*The Sun Also Rises, A Farewell to Arms*). Thomas Wolfe (*Look Homeward, Angel*) has groped for orientation, to recover with much emotion the record of his search. William Faulkner (*Light in August*) has depicted disintegration in the South since the Civil War. Erskine Caldwell (*Tobacco Road*) and Steinbeck (*Grapes of Wrath*) have been concerned with the impoverishment of land and people not only in the South. Farrell (*Studs Lonigan*) has represented the lack of horizon for the poor in the city. Dos Passos (*U. S. A.*) has shown the corrosion of rich and poor alike by shallow materialism. In the work of such novelists one may see the problems confronting the United States at home before the Second World War, presented with sociological realism and art, if not with sufficient insight.

The global character of this war, and the hope that out of it may come some progress toward a world order, make such a means of free communication as the novel freshly important. The vicarious experience it provides will help men to appreciate and enter into the cultural pluralism that is more and more the ideal. The Japanese novel *The Tale of Genji* by Lady Murasaki (about 1000) may help us to appreciate Oriental culture, as will India's *Mahabharata* and *Ramayana* which (although in verse) may be considered in the field of the novel; not to mention *The Arabian Nights* and the Bible stories which now belong to us as well as to the Near East. China is represented by *All Men Are Brothers* (14th cent.), a novel of adventure, by *The Red Chamber Dream* of Ts'ao Hsüehch-'in (17th cent.), and by *Monkey,* the adaptation of a folk legend.

Largely thanks to the Nobel Prize we have become familiar with Scandinavia through novels of Björnson, Selma Lagerlöf, Knut Hamsun, and Sigrid Undset, who received it respectively in 1903, 1909, 1920, and 1928. The Norwegian-American O. E. Rolvaag, with his *Giants in the Earth,* belongs in their company. Dutch novelists of note in the 20th cent. are Couperus, Fabricus, and Queride. Czech contemporaries were Jaroslav Hasek who wrote *The Good Soldier Schweik,* an influential satire on regimentation, and Carl Capek who wrote novels on social problems arising through mechanization, in addition to such plays as his famous *R. U. R.* Writing in Yiddish are the Polish novelist Sholem Asch, author of *Three Cities, The Mother, The Nazarene,* and I. E. Singer who treats of Jews in Poland and Lithuania in his best known work, *The Brothers Ashkenazi.* Next to the newspaper, the radio, and the revival of Tolstoy's *War and Peace,* it is Sholokhov's novels that interest us in the Soviet Union. **nunome** (Jap.). Literally, cloth meshes. In art, a pattern of small nodules, simulating the texture of regular weaving.

**Nuremberg, school of.** In 1662 Joachim Nützel, a councillor of the city of Nuremberg, established a private academy of art which was directed by Jacob von Sandrart and Elias Gödeler. There were lessons in life drawing and architecture, the latter taught by Gödeler. In 1674 Joachim vom Sandrart, a painter of international reputation, became the director of the academy. During his directorship the academy was made a public institution in order that, as Doppelmayr says, the youth, especially the children of the poor people, might learn the art of drawing and that in future the arts would continue to flourish in Nuremberg. After the death of Joachim von Sandrart several reforms were instituted, such reforms, however, did not prevent the decline of the academy during the 18th cent.

Joachim von Sandrart is the author of the *Teutsche Academie der Edlen Bau—, Bild— und Malerey—Künste* (published in two parts, 1675 and 1679). Sandrart, who borrowed freely from Palladio, Vasari and others for his theoretical discourses on art, summarized in these volumes the teachings of his school as well as the aims and aspirations of the art of his time. See Joachim von Sandrart. *Teutsche Academie der Edlen Bau—, Bild—und Malerey—Künste,* new edition with commentaries by R. A. Peltzer, 1925; Johann Gabriel Doppelmayr, *Historische Nachricht von den Nürnbergischen Mathematicis und Künstlern,* etc., 1730.

**oban** (Jap.). A large print, roughly 15 in. x 10 in.

**obelisk.** A four-sided, usually monolithic, pillar, tapering as it rises, and terminating in a pyramid.

**obi** (Jap.). Sash or belt worn with the *kimono*.

**object.** (Dadaist and surrealist usage.) A word adopted, alone, or in various combinations, in Dadaist and surrealist (qq.v.) usage, to designate an independent and self-contained structure or presentation consisting of a single entity, or assembled groups of entities, or parts of entities, and intended for contemplation as an aesthetic and imaginative stimulus; the distinctive feature being that the entities so used are not ordinarily regarded as artistic creations, or designedly of artistic quality, and their usual loci are not artistic contexts (e.g., wheels, sanitary fixtures, a dinner jacket, pieces of driftwood, stones, shoes, eggs, etc.). Such entities are taken from the non-artistic contexts in which they originally occurred, and are incorporated as they are, bodily, or in sections which do not impair the recognition of their original character, into some kinds of Dadaist or surrealist structures, whether paintings, *montages* (q.v.), sculptures, or other arrangements. They are sometimes treated, or "assisted", by the artist, signed, and exhibited in a manner usual for designedly artistic creations. There are many varieties of objects.

The earliest instance, in recent art practice, seems to have been that of the French artist, Marcel Duchamp, who, in 1914, exhibited a bottle-rack which he signed. Such "creations" were termed **"ready-made"** objects. (In popular French usage the term "ready-made", used as a noun, designates something factory-made, mass-produced, hence impersonal, without distinction.) The display of such entities, as Dadaist objects, served the Dadaists as a defiant, nihilistic, intellectually destructive act of mockery of traditional artistic values, forms, and substances; of contempt for contemporary artistic and social pretensions; and symbolically, of all traditional cultural values. It was calculated to shock by irreverence, plain statement and the violent dislocation of ordinary and habitual associations and relationships of daily life.

The surrealists later introduced (in the early 30's) many other varieties of objects, referred to generally as **surrealist objects** ("The surrealist object is one that is absolutely useless from the practical and rational point of view, created wholly for the purpose of materializing in a fetishistic way, with the maximum of tangible reality, ideas and fantasies having a delirious character." Salvador Dali.) Such objects include: **found objects** (e.g., driftwood, roots, volcanic remains), **found objects interpreted** or **assisted** (i.e., treated in some way by the artist), **mathematical objects** (mathematical and scientific models treated or viewed in such a way as to give them hallucinatory appearances), **objects of symbolic functioning** (e.g., fur-lined tea-cup; hair dresser's bust, crawling with ants, surmounted by a loaf of bread and an inkstand representing Millet's *Angelus*), **object-poems** (e.g., assemblages of miscellaneous things—a plaster egg, a candy butterfly, keys, etc.—arranged on a panel in conjunction with lettering and verse).

Something of the iconoclastic attitude of the Dadaists was carried over; and something of the scorn for the thoughtless assumption of a certain few materials as suitable for artistic manipulation, and not others. But primarily the surrealists were interested in

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

objects as the occasions, and objectifications, of fantasy, particularly of the Freudian, fetishistic, and obsessional kinds. Such objects were intended to serve also in the interests of a confusion between "art" and "non-art", between illusion and fact, and between the phenomenal, cognitive, imaginary, and the symbolically fantastic aspects of the physical world. The surprise and shock resulting from the new juxtapositions, both within the thing displayed, and in the manner of its display, were calculated to force a new and active attention, a re-examination and re-appraisal of the instrumentalities and activities of daily life; to release inhibited fantasies, causing the object of attention to become the objectification of the fantasy, in much the same way as children, primitives, and psychotics find magic, wonder, and terror in their environments.

Through the handling, treatment, and contemplation of such objects the non-artist became artist, in that he could objectify his imaginings and fantasies in visible images; lack of a developed "artistic" technique would no longer hinder imaginative release. This was felt to be highly desirable, for according to Surrealist ideology, modern bourgeois life has enforced the impoverishment of the life of the imagination, a loss of the sense of wonder, a dulling of perception, fancy, imagination, and the free play of association. See S. Dali, in *Le Surrealisme au Service de la Revolution,* December, 1931; D. Gascoyne, *A Short Survey of Surrealism,* 1935; "L'Objet", *Cahiers d'Art,* nos. 1-2, 1936; A. H. Barr, Jr. (ed.), *Fantastic Art Dada Surrealism,* 1936; H. Read (ed.), *Surrealism,* 1936; G. Hugnet, *Dada and Surrealsim,* Bulletin, Museum of Modern Art, vol. 4, 1936. —M.S.F.

**OCEANIA, ARTS OF.** Oceania includes the tropical and near-tropical islands often mentioned as the South Seas. The approximately 391,000 square miles of land are scattered throughout an area which is about one-eighth of the earth's surface and in 1941 was under the jurisdiction of eight nations: Australia, Chile, France, Great Britain, Holland, Japan, New Zealand, and the United States. The islands are usually divided into three groups: Melanesia, Micronesia, and Polynesia. Melanesia includes the island groups of New Guinea, New Britain, New Ireland, and as far east as Fiji, the northern limit being the Admiralty group, and the southern limit, Tasmania. Micronesia consists of many island groups extending east from southern Japan to Hawaii and south to the equator. The principal groups are the Carolines, the Gilberts, the Mariannes, and the Marshalls. Polynesia covers a huge triangular area with Hawaii, Easter Island, and New Zealand at the angles. The Australs, the Marquesas, Samoa, and Tonga are the better known islands that lie within this area.

The racial stock of each of these areas is the mixture of Negroid, Mongoloid, and Caucasian strains in greater or less proportions. In general, the Melanesians are more Negroid, the Micronesians largely Mongoloid, and the Polynesians more dominantly Caucasoid. In 1940 the indigenous peoples of Melanesia numbered about 1,400,000; those of Micronesia, about 100,000; those of Polynesia, about 330,000. Before the coming of the white man, the native population is believed to have been much more than double these numbers, but the commercial traffic of the whites brought about a depopulation trend that took its greatest toll during the last half of the 19th cent. By the beginning of the 20th cent., corrective measures had halted and reversed this population decrease so that in nearly all sections of Oceania the native population is now increasing.

Archeological evidences trace the native groups to Southeast Asia by way of the Malayan Islands. The distribution of the various peoples among the different islands

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

took place in a series of migrations which probably covered many hundreds of years and whose movements are lost in antiquity. In many instances the arts suggest a higher level of culture than was discovered by the early white explorers, who found neolithic customs rather than the types of civilizations that must have existed in earlier centuries to have produced such works as are evidenced in the excavations in New Zealand and in the remnants of huge megalithic structures to be found throughout the islands of Oceania. The introduction of new ways of living which included new religions, new tools, and also the problems which entered with the advent of the white race, brought greater changes in a single century than the Oceanic cultures had evidenced in all their known history, so that today it is only in isolated areas that the old ways may be observed. Nevertheless, even today the natives show their characteristic resistance to change by a tenacious hold on old traditions and, esp. in their arts and crafts, follow the same stylistic limitations that distinguish them from each other.

The ethnological boundaries are not an infallible guide to the arts and crafts to be found therein, but there are certain visual distinctions in the art styles that are worthy of note. Melanesian design, in general, is conspicuous for its free and dynamic movement and the decorative interweaving of dark and light areas and color accents; Micronesian design is characterized by greater precision of arrangement and perfection of craftsmanship, while Polynesian art is primarily one of structure or mass with less attention being given to applied decoration. Throughout Oceania chronology is uncertain. This is further complicated by attempts in modern times to simulate older or imported pieces for commercial reasons. Interpretation of motifs also is largely a matter of speculation, as the original significance has faded with the ages until very few of the native artists are able even to attempt an explanation. Conjectures of writers show a good deal of disagreement and in many cases appear to be preconceived notions not based on scientific inquiry. The use of many of the design elements may now be attributed merely to the strength of tradition which is apparent throughout the islands. Varied as are the expressions within a small given area, the arts are nonetheless subject to great restriction within each area so that the artist, while expressing his creative urge, still is conscious of what he may or may not do in expressing his own individuality within his design.

Considerable variation of opinion is to be found in writings about this complex area depending on whether the author is an anthropologist, geologist, ethnologist, archeologist, missionary, or merely a traveler. The study of Oceanic arts is usually approached from a social or religious viewpoint; this is entirely reasonable since it is only in rarer instances that anything created from the so-called "fine arts" aspect is apparent. In nearly every case, the art of the islands is an everyday art finding expression in household objects, tools, personal adornment, ceremonial objects, canoes, and weapons. In presenting a brief summary of these arts, it is not the writer's purpose to enter into either the social or religious aspects involved, but to deal with the stylistic variations and characteristics in the main geographical divisions.

**Melanesia.** The Melanesians are masters of their tools and their chosen mediums. The high degree of ornamentation found on even the simplest articles indicates an unusual aesthetic awareness; the richness of their decorative design cannot be overemphasized. Except for the art of the Maoris in Polynesian New Zealand, there is no parallel of this design consciousness in all of Oceania. The advantageous use of color accents and the skill demonstrated in the handling of the dark and light areas give evidence of this, but it is, above all, in their linear design that they exhibit their greatest mastery. The linear phase of their art is most noticeable in the area around the southeastern section of New Guinea commonly known as the Massim district, and includes the neighboring island groups off the coast.

The native artist uses the materials at hand: wood, stone, cocoanut shells, clam and oyster shells, gourds, feathers, leaves, cowrie shells, human and animal bones, clay, and lime. The pigments obtainable include black from charcoal, white from lime, red from burnt clay, and yellow from unfired clay. Additional colors are now being used where commerce has made them available. From these materials are created household objects such as bowls, spoons, lime spatulas, lime holders, gourd water bottles, stools, neck rests, adzes, axes, arrows, spears, and hunting clubs. Items of personal adornment include hair ornaments, necklaces, arm and leg band, ear and nose inserts, belts, aprons, and tattooing, including cicatrization. Ceremonial obejcts include shields, sacred tablets,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

masks and supporting staves, decorated skulls, images, drums, flutes, trumpets, bull-roarers, spears, arrows, clubs, stools, and small platforms.

Wood carving takes the position of prime importance in Melanesian art. Most of the wood is very hard although some kinds such as bamboo and gourd are softer. Stone adzes or axes are used for the preliminary blocking of the form; burning is often used to hollow out canoes and bowls; stone splinters, oyster shells, boar's teeth, or sharpened bone are used to refine the shape and to execute the design. A drill is fashioned by setting a sharp stone or bone tip into a stick which is rotated rapidly between the palms or whirled with a cord. Since the introduction of metal tools, the process of carving is easier and quicker, but the results tend to be much less perfect. After the carving is complete, color may or may not be worked into the design. The smearing on of pigment is typically Melanesian; the fact that in some localities the pigment does not necessarily follow the design would indicate that its purpose is not exclusively aesthetic.

The bowls of the Admiralty Islands, the canoe prows of the Trobriandes, and the wooden portrait statuettes of northwest New Guinea indicate the breadth of variety found in wood carving. The bowls of the Admiralty Islands are of hardwood, beautifully finished, with round, elliptical, spiral, or square legs. Decorative handles are often attached, but these are too insecurely fastened to be utilitarian in purpose. The bowls are stained with a dark pigment obtained from volcanic mud and are often finished with a high polish. The canoes of the Trobriandes, like those of many others areas, are works of art upon which the owner lavishes years of labor. The prow is usually covered with incised carving that gives it a particularly fragile and lacelike appearance. The statuettes of northwestern New Guinea are highly stylized human figures. There is neither the flawless surface perfection of the Admiralty Island bowls, nor the intricate pattern of the Trobriandes canoe, but there is a startling degree of realism combined with a conscious handling of the design elements that shows the artist's aesthetic sincerity and that has caused these sculptures to be described as caricatures.

Very beautiful and intricate carving is done on tortoise shell. The usual form of this work is a type of hair ornament commonly called a ***kap kap.*** Circles of exquisitely incised tortoise shell are mounted on pieces of polished sea shell obtained from a giant bivalve native to the region. The size and shape of the mount in relation to the incised work, the thickness of the tortoise shell, and the delicacy of the design vary with the locality. The carving is apparently done with a small file or saw handled much in the manner of the modern jig saw. The softness of the tortoise shell as a carving medium makes the lacelike quality of the design all the more remarkable. The finest examples are to be found in New Ireland and the Solomon Islands. These kap kaps are objects of exchange as well as ornaments. The wearing of them may be a privilege of tribal initiates or an indication of bravery, but more often is merely an indication of wealth. Variations of the kap kap theme include pendant discs worn on the breast or forehead or in the nose or ears.

Pottery is found in some sections of Melanesia: on the southeast coast of New Guinea, in the Bismark Archipelago to the north, one island in the Solomons group, one in the New Hebrides group, in New Caledonia, and in Fiji. That its use is not more widespread may be explained by the lack in other areas of clay in sufficient quantities for pottery although nearly all sections use small amounts of clay for coloring, for modelling parts of masks, or for adhesive grounds into which are set tiny seeds or shells.

Weaving is found in many places and pounded bark cloth similar to Polynesian tapa is made in some sections; in Melanesia, bark cloth is more generally used for ceremonial purposes than for clothing and the abundant use of mats noticeable in Polynesia is lacking in Melanesia.

Numberless species of highly colored birds are to be found throughout the Melanesian islands, and feather mosaic as well as other forms of feather work are used for ceremonial articles and for personal adornment.

Permanent body ornamentation may take the form of either tattooing proper or scarification. One group may tattoo, another may scarify, but it is rare to find both methods in use in the same area. Whether the ornamentation is merely decorative or is symbolic depends on tribal customs. In many places the decoration of specific areas of the body is an indication of age, degree of initiation into the tribe, or heroic deeds. It is not uncommon for a successful adult to have the greater part of his body covered with this ornamentation. Tattooing lends itself

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

to greater delicacy of design, but native ingenuity and patience have produced patterns of startling intricacy through cicatrization.

In most Melanesian art there is a noticeable refinement of line, a perfection of surface finish, and a conscious selection of the field to be decorated. The predominance of the bird motif is apparent, especially in the Massim district. It is a favorite in nearly all sections as a motif for hair ornaments. The pig, dog, crocodile, boar, cassowary, dugong, fish, and plant life are all used for decoration. The presentation may be very realistic or very stylized depending on the island area; as a rule a given section handles all its motifs in the same manner and it is unusual to find realistic ornament where there is a high degree of stylization. In the section near the Torres Straits between Australia and New Guinea the ornamentation reaches its highest degree of realism, but design consciousness is comparatively weak. Other sections of Melanesia show a comparatively high degree of stylization and a correspondingly advanced degree of design quality. In the Massim district where the art expression reaches its peak, most of the motifs are so highly stylized as to be practically unrecognizable. Geometric pattern elements are found in all areas. Much of Melanesia, especially New Guinea, employs motifs common in the late Shang period of China such as angular spirals and isolated eyes, while the Massim district in particular shows many features of the late Chou period as well as many motifs primarily associated with Indonesia such as the streamer, double spiral, and interlocking spirals. This similarity is too great to be the result of chance and is an important factor in suggesting the probable periods and directions of migrations into the Pacific area. Designs are often clan property; certain designs may be taboo in various clans. Seldom, if ever, are any two designs alike and yet the patterns of each area are distinctive and are not likely to be confused with the design treatment from another section.

**Micronesia.** The largest and most striking of the Pacific area megalithic structures are to be found in Micronesia on the island of Ponape in the Carolines. Huge pieces of basalt have been laid one on the other to construct miles of walls that are thirty feet high in some places and often fifteen feet thick. The streets were apparently waterways and the entire city covers about eleven square miles. The problem of their construction remains unsolved.

Aside from the puzzle of the megaliths, Micronesian art is not striking for a high degree of artistic achievement other than that of technical excellence. Utilitarian articles are carved from wood, bone, and shell, but there is usually little or no decorative design added. The Micronesian ax is a piece of the giant tridacna lashed to a wooden handle. Spears are made of shark's teeth inlaid in wood. Where fibre is used to lash together parts of implements, there is often a design worked in, but the Micronesian apparently gave his major attention to the use for which his articles were intended, placing form, durability, and perfection of finish above the more obviously decorative aspects.

The houses of the Micronesians are less pretentious than those of the rest of Oceania and for the most part are unadorned. The arts of pottery and loom weaving are known in Micronesia, but the extent to which they are practiced is uncertain. A fibre cloth with colored patterns is made and plaiting is employed throughout the area, but no tapa cloth is made. A fibre vest of unusual thickness and a snug fitting helmet serve the purposes of the war shields found elsewhere in the Pacific area. In the Gilberts, no timber of sufficient size is available for canoes so the natives must rely on driftwood and build large canoes by lashing together odd-sized planks.

Personal ornamentation consists of complex arrangements of assorted objects as shells, rings cut from shells, and teeth, a decided preference being shown for shark's teeth. Their patterns appear primitive and sometimes crude as compared to the more elaborate organizations of Melanesian and Polynesian jewelry. Tattooing and scarification are both practiced in Micronesia, the latter being most frequently used to produce rows of dots on the flesh. With very few exceptions, Micronesian designs are technomorphic in character. There is some human sculpture in wood, but these figures appear more primitive than stylized.

The poverty of information about or evaluation of Micronesian art seems reasonable in the light of their obvious preference for elaborately ingenious utilitarian devices such as their ocean charts which are narrow strips of wood formed into a lattice on which the islands are indicated and which could not be properly classified as art. Most authorities seem agreed that the exploitation of the Micronesian islands took place at a very early date. It is also the general opinion

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

that these were the last of the island groups to be settled, and in the writer's opinion this may be an explanation for the viewpoint that Micronesian art appears to be that of a people starting anew in their art expression. Their works appear to lack tradition except in such isolated instances as pottery and weaving which obviously had a relationship to those of Indonesia. The frequent resemblance of Micronesian art to that of earlier Japan has been noted, but as yet has not been properly explained. Extremely opposing speculations exist as to the source and character of the elaborate coral reef structures on the island of Ponape for instance, and at present it seems impossible to analyze Micronesian art on any kind of a derivative basis. The people are more conglomerate than those of the other island areas and their works elude exact definition.

**Polynesia.** Because the islands of Polynesia are so widespread, it is not at all surprising to find that the art interest varies greatly in the different sections. The **Maoris** of New Zealand show a decided preference for carving in wood, bone, or stone. Even the Maori type of tattooing is a kind of carving. The Maoris feeling for design excels by far that of the rest of Polynesia and elaborate carving is done on the prow, hull, and tail pieces of canoes; on steering oars and water balers; on caskets, monumental sepulchers, digging implements, doors to storage pits, gourd drinking vessels, weapons, ornaments of human bone, frames of drag nets, floats of seine nets, stone sinkers for submerging the nets, musical instruments, and even the carving tools themselves. The Maori has developed the carving technique to near perfection, but carving in other parts of Polynesia fails to reveal a comparable refinement of line or such superior craftsmanship. A contrast to Maori carving is to be found on the Catham Islands nearby. Here carving is very crudely executed in pumice stone or on the smooth bark of a native tree. As there is no timber of sufficient size for canoes, bundles of leaves or stalks are bound together and a prow of wood is added and carved with very simple bird or human patterns. The greater part of Polynesian carving lies between these two extremes, but in most areas its importance is overshadowed by other arts. In the islands of the Marquesas, much wood carving is done and although it is by no means the cruder type found in the rest of Polynesia, it lacks the delicacy and sophistication of the Maori carving.

It is known that New Zealand was inhabited at the time of the Polynesian migration. Polynesian records describe the earlier people as being of an inferior culture, but it is more than possible that these people had a culture superior to that of the Polynesians. Excavations have revealed evidences of prehistoric craftwork that would indicate an even higher cultural level than that of the historical Maori.

Throughout Polynesia are to be found remnants of earlier cultures. In eastern islands these evidences are found in the megalithic ruins of the sacred places, or **marae** of the Polynesians, which were paved areas, sometimes surrounded by walls, and sometimes containing platform structures. In the islands of Hawaii and Tahiti it is not unusual to find all features in one place. Many of these sites were originally surmounted by large figures of stone or wood in conventionalized human forms. The islands of Tonga and Samoa in western Polynesia do not have the *marae,* but Samoa has numerous flat-topped mounds which appear to have been burial places, substructures for temples, or areas constructed for defensive purposes. That this megalithic style was developed by the Polynesians before they settled in their present area is indicated by the parallel forms that occur throughout many islands which had no inter-communication.

Featherwork is beautifully done in many places. The colorful plumage of native birds is fastened onto matting to produce intricate mosaic patterns. Elaborate headdresses are made in nearly all the islands. The artists on the islands of the Marquesas are noted for their beautiful feather coronets. It is interesting to note, however, that in the islands of New Zealand where such superior wood carving is done and where such emphasis is placed on pattern detail, the featherwork is less ornate than in other areas; feathers are used singly in the hair and the feather robes show little conscious arrangement.

Loom weaving is unknown in most of Polynesia; instead the art of plaiting has been highly developed. Flax is sometimes available, but more often grass or leaves are used. Mats and robes of unusually large size are made by this slow and tedious process. Colored designs are worked in and often human or dog hair is worked in to give a soft fluffy appearance. One type of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

mat has long fibres woven into one side and combed out when the piece is finished so that while one side is smooth, the other is covered with a shaggy fluff somewhat resembling fur. A very coarse, plaited robe which is water-repellant is in common usage throughout the islands. In New Zealand, looms are used and weaving is done with dressed or undressed flax. The use of a robe is determined by the kind of feathers or hair woven into it. Baskets, fans, bowls, and platters are also plaited with colored patterns. Where the Melanesian or the Polynesian Maori carves bowls, tool handles, and countless other objects, the average Polynesian uses his endless variety of plaitings.

**Tapa cloth,** the most universally known product of Polynesian craftsmen, is made from the inner bark of any of several native plants. This bark is soaked in water until the pulp is soft and starts to fall away from the fibres; then the pulp is scraped off, laid on mats, and pounded until it is a smooth sheet. Several layers are put on to insure uniform thickness and to give the desired size. An instance of the subtlety of appreciation of some natives, particularly those of Hawaii, for the technical achievement in tapa manufacture is shown in the practice of carving the pounding surface of the implement which is used to beat the fibres together; this produces what is called water-marked tapa which is considered very superior. Designs are applied freehand with brushes made from frayed twigs or, as is more frequent, the design is applied by means of pattern blocks. The motifs used on tapa display the amazing ability of the Polynesian to arrange almost purely geometric forms into an infinite variety of patterns with changes occurring even in the repetition of a single surface unit.

**Tattooing** is almost universally practiced and is generally a mark of rank, slaves being forbidden to tattoo. Maori tattoo takes the form of cicatrization, but the patterns are composed of very fine lines rather than the more lumpy scars generally associated with this type of ornamentation. Subtle distinctions are to be found in the tattoo patterns of Polynesia, Melanesia, and Micronesia although a similarity exists in the geometric quality of many of the designs.

Technomorphic designs predominate in most of the wood carving except where the human or animal figure is used for some special reason. The remnants of early stone sculpture show very crude, simplified, human forms. The two great exceptions to this tendency are the works done in the islands of the Marquesas and New Zealand. Both of these areas show art developments that are unlike those of the rest of Polynesia. The spiral of the Marquesas and certain stylistic tendencies in delineating the human face show a marked resemblance to those found in China during the late Shang period. The art of New Zealand gives even stronger evidence of Chinese influence for it includes not only the motifs found in the Massim district of Melanesia which have been mentioned above, but many more purely Chinese elements such as the serpent forms and the double spiral forms of the late Chou period in China. It is evident that the two Polynesian areas mentioned were affected by waves of oriental influence which did not reach the rest of Polynesia and which account for the differences between their arts and the art of the other Polynesian islands.

The greatly intensified interest that is now centered around the islands of the Pacific area will undoubtedly produce much additional evidence to alter or substantiate existing theories in regard to these peoples and their arts. See British Museum, *Handbook to the Ethnographical Collections,* 1925; Brown, J. MacMillan, *Peoples and Problems of the Pacific,* 1927; Buck, Peter Henry, *Vikings of the Sunrise,* 1938; Edge-Partington, James, *An Album of the Weapons, Tools, Ornaments, Articles of Dress, etc., of the Natives of the Pacific Islands,* 1898; Haddon, Alfred Cort, *The Decorative Art of British New Guinea,* 1894; Heine-Geldern, Robert, *L'Art Préboudhique de la Chine et de l'Asie du Sud-Est et Son Influence en Oceanie,* 1937; Reichard, Gladys A., *Melanesian Design,* 1933. —M.C.G.

**ochre.** A wide range of colors is comprised by this term, all of them natural earths characterized by the names yellow ochre, golden ochre, red ochre, and brown ochre. All are silica and clay mixtures which owe their color to iron oxide. This is in a hydrous form in the yellow ochres and anhydrous in the red. As a painter's pigment, ochre has been known since prehistoric times. —G.L.S.

**octave.** See interval; ACOUSTICS.

**octave instrument.** See ACOUSTICS.

**octavo.** See book sizes.

**octodecimo.** See book sizes.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**ode symphony.** A choral symphony; e.g., Beethoven's Ninth.

**Odo yaki** (Jap.). Pottery made in Tosa province.

**Odonic notation.** See NOTATION.

**Odysseus** (L. Ulysses). A leading Greek hero of the Trojan War, famous for his nimble wit, wise counsel, ingenuity and endurance in overcoming the difficulties encountered during his ten years of wandering before he reached his home in Ithaca. The story of his adventures is told in Homer's *Odyssey*. His exploits were often pictured in Greek vase paintings. Postclassical sculptors who have taken him as a subject include Pradier and Eric Gill. —W.R.A.

**oeil-de-boeuf.** A circular or oval window.

**oenochoe.** A Greek wine-jug, one of the loveliest shapes in the history of pottery, with a delicately curved handle and usually a trefoil-formed mouth. The 7th cent. B.C., Rhodian jugs are broad-bellied, with a volute handle; they are decorated with friezes of birds and animals, painted in brown on a cream slip. Athenian ones are slimmer and more delicate in shape, and often have a chaste panel of decorative painting on the side. 4th cent. B.C., Apulian ware is characterized by a thin, tapering body, tall stem, and high-curved handle. —W.R.A.

**offertory.** See MEDIAEVAL MUSIC; psalmody; Mass.

**offset.** (1) Transferring an impression from a proof on which the ink is still wet to an unbitten plate or another paper. (2) Term applied to ink when it soils a page that has been piled upon it before the ink was dry. (3) A comparatively narrow set-back in the length of a wall, as when the face of a wall is not one continuous surface, but sets in by horizontal jogs, as the wall grows higher and thinner.

**offset, soft ground.** A method of transferring a chalk drawing to a copper plate for intaglio printing. The proof resembles crayon lithography somewhat more than the regular soft ground etching, which tends to resemble a pencil drawing. The masses of dark are richer and easier to handle. —K.K.

**offset soft ground** (an intaglio process). The offset soft ground is a tonal process resembling lithography more than ordinary soft-ground. As in lithography, the drawing is made with dark crayon so the artist can see the probable result instead of working blindly as in the case of etching.

The advantage over lithography is that the drawing on paper is made obverse and reverses on the plate to come back obverse in the proof, a great advantage in portraiture. One has absolute control over the most delicate passages fugitive even in experienced hands. The darks have the richness, depth, and the velvety quality of acquatint; large editions can be made without injury to the plate or loss of delicate tones. It does not take an expert to pull large editions as in the case of lithography.

In this type of soft ground the drawing is made on a piece of paper with charcoal, conte or similar type of crayon. A special soft ground is rolled on the plate. The drawing is transferred to the copper plate, coated with a special soft ground, by applying the pressure of the etching press. The plate is now dusted with asphaltum which sticks to the plate only where the crayon dust of the drawing has not already stuck. The plate is rinsed, dried, and heated, till the asphaltum becomes a very hard ground. The offset of the crayon drawing which is still imbedded in the ground is now washed out with cotton and alcohol, leaving bare copper wherever this drawing had been. The areas of bare copper are broken up with an acquatint ground and the plate is bitten with or without stopping out. The plate is now printed like any other intaglio plate. This process was invented by Alexander von Kubinyi of Munich. —K.K.

**off-street parking.** See CIVIC PLANNING.

**Ofuke yaki** (Jap.). Pottery made in Owari province.

**ogee.** A molding with an S-shaped profile. See cyma recta; cyma reversa.

**ogive.** The arch or rib crossing a Gothic vault diagonally. A pointed arch.

**oil varnish.** See drying oils.

**oils.** Used chiefly for surface films and for painting mediums, the vegetable oils have included those from the flaxseed (linseed), poppy, walnut, and others (see also drying oils). All belong to the class of chemical compounds known as **esters.** To be capable of drying or forming a firm and hardened film on exposure to the air, they must con-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

tain a number of double bonds or points at which oxygen can combine with the fatty acid. The drying process is largely one of addition of oxygen. Historically, they have been best known from the early part of the 15th cent. but there is extensive evidence that they were used before that time in European painting. Painters of the Far East have never shown an interest in them, though rare examples like the representations on the doors of the Tamamushi shrine at Nara, Japan, indicate that the drying oils have been known to the Orient. —G.L.S.

**ojime** (Jap.). An ornamented slip-bead used on the cord which suspends the *inro* (q.v.) from the belt. The *ojime* is slipped down over the cord with slight pressure to keep the various parts of the *inro* together. —J.A.M.

**Old Bering Sea culture.** See ESKIMO ART.

**old copies of paintings.** See FORGERIES OF PAINTINGS.

**Old Nankin porcelain.** See CERAMICS II.

**oleoresin.** Sometimes given to combinations of oil and resin, this name is usually applied in the fine arts to a natural balsam or soft semi-liquid which exudes from coniferous plants. Such a material has been employed as an ingredient in surface films and to a minor extent as an ingredient in painting mediums. The best known are Venice turpentine, Strasbourg turpentine, Canada balsam, and copaiba balsam. All are apt to form brittle and dark films on long standing. —G.L.S.

**oliphant.** See MUSICAL INSTRUMENTS.

**olive branch.** In classical art, a decorative pattern with small elliptical pointed leaves opposite each other on a stem; a symbol of peace; made into a wreath a victor's prize at the Olympian games in ancient Greece. —L.T.S.

**Olmec.** A term originally applied to peoples living in southeastern Vera Cruz and at one time in central Mexico. No arts and crafts have as yet been surely identified as the work of these people, but the term has tentatively been applied to highly stylized sculptures of men and tiger gods found in southern and central Mexico. —G.C.V.

**olpe.** A leather receptacle for oils or liquids. A wine pitcher, similar in shape to the oenochoë (q.v.), but more cylindrical in body.

**omphalos.** See altar.

**one-point perspective.** See PERSPECTIVE.

**one stroke painting.** See CHINESE ARTS.

**one-way glass.** See GLASS AND GLASS-MAKING.

**Onohara yaki** (Jap.). Pottery made in Tanba province.

**Onto yaki** (Jap.). Pottery made in Ise province.

**open-air museum.** See SCANDINAVIAN ART.

**open chapel.** An apse-like (occasionally church-like or even mosque-like) adjunct of the main church of Mexican 16th cent. monasteries where services were celebrated for large congregations of Indians standing outdoors in the *atrio* (q.v.) to which the chapel opened out broadly. (Occasionally also in Peru.) —J.Mc.

**open cut.** See CIVIC PLANNING.

**opened.** *Book.* The leaves of a book cut with a paper-knife.

**OPERA.** NATURE. Opera is an art form expressing life through speech, song, gesture, and picture. It is both visual and auditory, and cannot therefore be a purely musical form, in spite of the fact that it is sometimes so considered. Opera's wide-spread popularity can be traced to this broad psychological basis, which has assured its existence in the past, against much opposition, and will assure its existence in the future. In no other single art form can life or mankind be so comprehensively or directly mirrored; here we live or relive, in psychological projection, all the pleasures, pains, the ambitions, hopes and disappointments of our existence.

Among music-forms opera has been, in many ways, the least artistic. Its obvious pageantry has long lent itself to superficial, inartistic display, vocally as well as theatrically, in France under Louis XIV, in England under Charles II, and in the personality intrigue and social set-up of many of the leading opera houses today.

When an opera will be created and performed in which the textual, tonal, scenic, and histrionic elements are all of equally high artistic levels, an art-form would result superior to any thus far created. It is the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

wide discrepancy among its elements (excellent music, bad acting, ridiculous staging, poor libretti) that so often reduces opera to a low level.

The domain of opera falls roughly into two categories; that dealing with religion or other symbolism and ideologies (which is really the domain of oratorio) and that dealing with human emotions of love, hate, cruelty, intrigue and comedy. If we go back to the rituals of primitive peoples, to the sagas of early civilizations, and to the dances and pantomines of past eras, we can trace opera as a psychological projection of such basic urges, as those of acquisitiveness, sacrifice, cruelty and others. (A scholarly analysis of opera, on this basis, has been made by Dr. Ernst Lert in his *Opera Complex.*)

FORMS. ***grand opera*** (Ger. *Ernste Oper, Grosse Oper;* It. *opera (seria)*; Fr. *grand opéra, tragédie lyrique*). Essentially a tragedy set to music with tragic dénouement, no spoken dialogue (*Iphigenie en Tauride, Tristan and Isolde, Rigoletto*). Today also, loosely, opera *in the grand manner* with famous cast, large orchestra extravagant scenery and action, high admission prices.

**Opera comique** (Ger. *Singspiel*; Eng. opera). (Cherubini, *Les deux journées.*) A form of opera in which either the dénouement is happy or the dialogue is spoken, or both. Not the equivalent of comic opera since it need not contain any comic element.

**Opera buffa** (Ger. *Komische Oper*; Eng. comic opera). A form of opera with dialogue (**secco recitativo**), interspersed between soli, ensembles and choruses and dealing with comic or light subject matter. This form developed from the "interludes" which had been used between the parts (acts) of the opera seria or of the spoken play. (Mozart, *Cosi fan tutte*; Rossini, *Ill Barbiere di Siviglia;* Pergolesi, *La Serva Padrona;* Cimarosa, *Matrimonio Segreto.*)

**Opera bouffe.** French light opera bordering on musical comedy, extravaganza or vaudeville.

**Operetta** (Fr. *Operette*; Ger. *Kleine Oper, Operette*). A diminutive opera in length and content, making no pretense to seriousness. A musical stage entertainment. Closely allied to opera bouffe. (Gay, *Beggars Opera (Ballad Opera)*; Mozart, *Schauspieldirektor*; Rossini, *L'inganno felice*; and the works of Gilbert & Sullivan, Johann Strauss, Herbert.)

**Music drama** (It. *dramma per musica, dramma musicale*; Ger. *Musikdrama*; Fr. *drame de musique*). A form of opera in which all elements are equally conceived: plot, text, action, scenery, music. It forms the basis for the works of Monteverde, Gluck, and was brought to its highest perfection by Wagner in his *Ring des Nibelungen.*

Singspiel (Eng. song-play). A German form of opera with secco recitativo but the serious import of opera seria. Loosely used as equivalent to grand opera. (Mozart, *Entführung aus dem Serail*; Beethoven, *Fidelio;* Weber, *Freischütz.*)

**Melodrama** (It. *melodramma*; Ger. *Melodram*; Fr. *melodrame*). A form of opera in which spoken dialogue is used against an instrumental background as accompaniment. It is an entire work of accompanied recitative. (Beethoven, *Music to Egmont*; Schumann, *Manfred Ballads*; Mendelssohn, *Midsummer-Night's Dream.*)

**Recitative** and **Aria.** A division of the vocal parts of opera resulting from the attempt to express all phases of the libretto with pitch inflection. As a result, we have a series of gradations extending from the simple spoken word, with no fixed pitch inflection, to the **recitative secco**, a form of declamation with little or no accompaniment, but with some attempt at pitch variation; to the **accompanied recitative** (**recitativo strumentato**) in which the accompaniment helps to control the vocal pitch, and at the same time adds to the dramatic effect; to the **mezzo-recitativo** of Gluck in which voice and orchestra complement each other; to the **arioso** of Monteverde and the **melos** of Wagner, in which the vocal line leaves recitative and approaches melody without, however, being strictly metric; to the **aria** itself, in which beauty of melodic line replaces declamation. The aria is the opera equivalent of "song" (q.v.) but lacking the close connection between melody and text. In the opera aria, action is largely suspended and the lyric, emotional element is given free reign. The "patter" songs of Sullivan, also the famous *Largo al Factotum* are forms combining recitative and aria elements.

**Recitative** is essentially concerned with the narrative or descriptive elements of opera, too rapid or too prosaic to fit into the more slowly moving, emotional and essentially smooth aria. But a recitative may readily contain arioso phrases, and an aria may as readily contain elements of recitative.

HISTORY. Opera, as this is generally understood, originated as an art form at the end of the 16th cent. but its roots go back much further. Gesture and chant have accompanied

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

life throughout antiquity. The marked development of 1600 resulted from an attempt, deliberately made, to free music from the restrictions of the previous polyphonic styles. Both poets and musicians were involved: Bardi, Corsi, Rinuccini, Peri, Caccini. Songs with lute accompaniment (hence homophonic) were already known and practiced. For the dramatic element the Greek tragedies of Sophocles, Aeschylus, and Euripides were studied. The urge to write *drammae per musica* had manifested itself in Vecchi's *Anfiparnasso* (1594), a madrigal opera; in the masques, a Renaissance form of musical entertainment; allegorical and mythical plays with music and elaborate theatre; in Poliziano's *Favola di Orfeo* (before 1500); and last, but not least, in the *laudi spirituali*. The ingredients of opera were thus already present. The development at 1600 was not an entire beginning, but rather an adaptation of these established elements to the new homophonic idiom.

The chief new elements of these early attempts (*ars nova, nuove musiche*) at opera (*Dafne* by Peri with text by Rinuccini, *Euredice* by Peri and also by Caccini) were monody with accompaniment, the juxtaposing of the horizontal, melodic element, and the vertical, harmonic element of music. But the impossibility of using melody to depict all phases of the drama, esp. the epic, soon resulted in the use of recitativo secco for the narrative parts. The *stile rappresentativo, musica parlante,* dominated the earliest versions, but the participation of singers and the need for lyric expression soon developed a more melodic style (Caccini). We find it also in the secular cantatas of that period. Nevertheless, recitative and not lyricism remained the main distinguishing feature of this first period. Interest quickly spread from Florence to other localities and the social and superficial by-products made opera a thing for only royalty and festive occasions.

The first composer to leave an indelible stamp on opera was Claudio Monteverde (1567-1643). He was first of all an excellent musician, and thoroughly in sympathy with the monodic development. His chief contributions were: a marked increase in the effective use of harmony, including, of course, dramatic effects of dissonance (dominant-seventh chord); the use of instrumental color and thematic material for scenic and histrionic description; and the introduction of a form of mezzo-recitativo (arioso), linking the earlier recitative with the later aria. (*Orfeo,* 1609). In his works we find the first examples of Wagnerian idiom (melos as arioso).

In 1637 the first opera house was built in Venice. Further development of rhythmic melody characterized the works of Cavalli, Cesti and Legrenzi. Meanwhile the Italian fondness for the opera form spread, and many performances were held in various cities.

Alessandro Scarlatti (1659-1725) the foremost representative of the **Neapolitan School,** divided recitative into secco and strumentato and introduced the **"da capo" aria,** the A-B-A form, thus using the basic element of all musical forms: repetition. (Such repetition is a purely musical characteristic, and is opposed to the continuity demanded by the epic element.) In the meantime the theatrical element of opera began to usurp the field and the talented followers in the Neapolitan School wrote often for vocal display rather than for dramatic verity. The use of *castrati* lent impetus to this tendency, and in this form, opera spread to such widely separated points as Madrid, Copenhagen, Lisbon, St. Petersburg, Dresden, and Vienna.

Opera was introduced into France by Lully (1632-1687). To the imported Italian elements, he added the typically French "ballet" idiom. His recitative was adapted to the poetic meter, and the instrumental interludes were extended. (Cambert composed an early example of French comedy with music in the *Pastoral d'Issy,* 1669). Lully's style in music was similar to that in literature of his contemporaries Corneille and Racine. The connection between opera and dance is seen in the founding of the Academie Royale de Musique et de Danse (1672).

The Lully tradition was carried on by Rameau (1683-1764) with continued emphasis on dramatic truthfulness, refining somewhat the melodic, harmonic and rhythmic elements.

In England Purcell (1658-1695) developed English opera from the masque (equivalent of the French *masquerade*). This form, with incidental music, was distinctly English; however, Italian opera was at the time known also in England. Purcell was influenced both by Italian and French idioms but added an austere musical element which was distinctly his own (*Dido and Aeneas*), not unlike certain moods in **Shakespeare.**

The German form which served as a precursor to opera was the Singspiel, and German opera developed with Reinhard Keiser (1674-1739). The first singspiel opera was *Dafne*

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

(1627) by Schütz. Keiser is associated with Hamburg opera, where he wrote more than one hundred works for his theatre. An easy melodic gift, but little serious workmanship, makes all of them of mere passing interest.

The cosmopolitan character of opera is strikingly revealed in the works of Friedrich Händel (1685-1756), for here we find a German composer writing Italian opera in England and bringing the form to new, high levels of artistic achievement. His adaptability to the demands of particular occasions and the richness of his genius made his operas dominate the field. His early activity at Hamburg with Keiser, his trip to Italy and his acquaintance with French opera enabled him to utilize these sources and at the same time give them the stamp of his own superior talents. Rinaldo, written in 1711, combined these elements and gave opera its true international stamp. Händel's greatness as opera composer lies chiefly in the fact that he was willing to use any and all of the devices, musical and theatrical, that go into the making of the opera-form. To further his work he became associated with the Royal Academy of Music. He composed with consummate ease and his operas contain, besides their excellent music, many empty formalisms dictated by extraneous circumstances, some of the arias being actually composed by the castrati taking part.

The Händel period of operatic history was followed by the development of various subforms and various parts. Ensembles were enriched by Piccini (1728-1800) and for the first time effective finales were used as a consistent feature. But as an art form opera did not advance until the reforms of Gluck.

Gluck (1714-1787), following the principles of Monteverde, tried to overcome the fundamental conflict between the separateness of musical forms and the continuity of action. He replaced the set forms of recitative by using an accompaniment which, combined with the vocal line, produced a single artistic unit. His principles are clearly set forth in his preface to *Alceste*. Differences between recitative and aria diminished, and the empty vocal display disappeared. He worked chiefly in Paris. Among his operas are: *Iphigenie en Aulide, Iphigenie en Tauride, Orfeo, Alceste* and *Armide*. At the same time Piccini upheld the Italian traditions, which resulted in a famous controversy between him and Gluck.

We come to Mozart (1756-1791). He is usually not considered a reformer or innovator, yet the unsurpassed musicianship of his work, and a seldom appreciated genius for true musical portrayal of even obscure and subtle psychological problems (drama in the best sense) added operas of a very distinct character to the literature. In *Cosi fan Tutte, Le Nozze di Figaro,* and *Il Giovanni* he brought Italian opera to its highest point. Building upon the attempts of Keiser, he improved the German Singspiel form in *Entführung aus dem Serail* and still more so in the *Zauberflöte*. Accompanied recitative received new values and the operatic finale, as in the second act of *Figaro* and that of the *Zauberflöte,* has yet to be surpassed. Whereas Händel has integrated all elements of opera, Mozart does so primarily with the musical elements and his operas remain musicians' operas *par excellence*. Mozart, in opera, was the greatest and last "Italian" up to that period, as Palestrina was the greatest and last of the Netherlanders.

Beethoven's *Fidelio* is the most conspicuous example of a great work which is not essentially opera. The characteristic dramatic intensity and sincerity are there, so also the Beethoven profundity and truth, but they do not make theatre, a necessary element of opera. Apart from a non-vocal idiom (the voice is treated as an orchestral part) stage drama, as it is evidenced in the obvious finale and the aria as such, is missing. *Fidelio* is essentially non-theatrical. If Mozart wrote the musician's opera, Beethoven, in *Fidelio,* wrote the musician's tonal drama.

Opera in the 19th cent. divides into two types: pre-Wagnerian and post-Wagnerian. The former (early 19th cent.) continued along previous lines. In Germany, with Weber's *Freischütz,* German romantic opera was raised to a high level. This type, based upon legend or saga, characterized also the works of Spohr and Marschner. In France the serious import of *Fidelio* had its effects on opera seria in the works of Cherubini (*Watercarrier*), Meyerbeer (*Robert le Diable*), Halévy (*La Juive*), and Spontini (*La Vestale*) with the elaboration of a heroic element. Opera comique continued with Auber (*La Muette de Portici*) and Boildieu (*La Dame Blanche*). In the meantime a more lyric form developed with Gounod (*Faust*), Thomas (*Mignon*), Bizet (*Carmen*), Massenet (*Le Cid, Thaïs*) Saint-Saëns (*Samson et Dalila*). In Italy the traditional form is found in the works of Bellini (*Norma*) and Donizetti (*Lucia di Lammermoor*).

Verdi (1813-1901), next to Wagner, dominates the field. He began with insignificant traditional Italian works, but, with Ernani,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

1844, we find the first attempt to lift mere agreeableness of sound to the dramatic level of tone-portrayal. At the same time the spirit of the Italian people begins to shine through. In *Rigoletto,* Verdi becomes cosmopolitan in styles, assimiliating French influences (Meyerbeer) and, in dramatic force approaching the German style. Although Wagnerian influences may be traced in Verdi's later operas, these, in their main characteristics, could have been written as a natural development of the composer's style itself, which passed from the superficial to a highly dramatic, tonally forceful, and psychologically sound style in *Aida, Othello,* and *Falstaff,* the last written when Verdi was 80 years old. Verdi's operas are true operas. With their musical richness and power, they also retain good theatre, colorful staging, effective ensemble and soli, and good stage plots in spite of some very poor libretti. A continuance of this tendency ultimately may readily have led to the Wagnerian concept.

In the meantime Wagner (1813-1883) himself finally brought the original opera concepts of the Florentine Camerata to their highest development. In his music drama he develops a complete psychological synthesis of plot, music, stage and action. The basic tonal means of securing this integration is the **Leit-motiv,** a tonal figure to symoblize objects, characters, and ideas. It is a highly developed counterpart of the "theme" idea in instrumental composition (fugue or sonata forms), or in tone poems such as *Eulenspiegel.* Musical forms as such, aria, set finale, etc., were discarded and recitative strumentato is elaborated into a "melos." Wagner was peculiarly fitted for this task—he was a music philosopher (*Oper und Drama*), and wrote the texts to his music dramas. As a result there is a unity of whole which has never been equalled. Since vocal utterance is limited, no matter what pitch line is used, it was natural that dramatic force and tonal color should be obtained through the orchestra, and this Wagner developed to its highest point. Individual characteristics of his style are text alliteration, chromaticism, certain metric patterns and complex chordal structures. Following *Rienzi, Tannhäuser, Der Fliegende Holländer, Meistersinger,* his artistic concepts reached their highest point in the *Nibelungen Tetralogy*: *Rheingold, Walküre, Siegfried, Götterdämmerung. Tristan und Isolde* is the lyric opera *par excellence*: *Parsifal* is a semi-sacred stage drama which leans toward the scenic oratorio.

The breadth and scope of the Wagnerian idea, esp. when voiced at Bayreuth (1876), where a special theatre had been built, made further development along these lines improbable, if for no other than practical reasons: cost of equipment, personnel, etc.

In Germany, Richard Strauss (1864-) introduced a new psychological or better psychopathic element into opera, shown by his choice of Wilde and Hoffmansthal for libretti. The nature of his character delineation is not unlike that of Mozart, but the characters themselves are widely different. Excellent tonal painting and orchestral color dominate, with the vocal line an elaboration of the Wagnerian arioso (*Salomé* and *Elektra*). The cleverness of Strauss as colorist, as portrayer of Freudian complexes makes his work highly realistic. Yet this realism differs in the complex tonal structure from the cruder realism of the Italians — Mascagni (*Cavalleria Rusticana*) and Leoncavallo (*Pagliacci*). Puccini (1858-1924) carried on the lyric opera (*Manon Lescaut, Tosca, Madame Butterfly*) and introduced, for the first time, an American theme in *Girl of the Golden West.*

Although scenic opera has not entirely passed out of the picture (Kaminski; Jurg Jentsch; Milhaud; Christophe Colombe) the central trend of present day opera is toward greater subjectivity and smaller frames. Furthermore a socialistic element has been introduced and the greatly enriched tonal resources have turned the attention of composers to new musical forms such as suite, passacaglia and rhapsody (Berg: *Wozzeck*), and carries speech-song into the extra-tonality field.

Chamber opera is in the making. This is not grand opera merely reduced, but entirely conceived as a smaller form, in plot, in vocal and instrumental utterance and in theatre. Hints of this tendency are found in Hindemith, *Neues vom Tage;* Strawinski, *Oedipus;* Krenek, *Zwingburg;* Weill, *Bürgschaft.*

The emphasis on song, which is also characteristic, may lead to the development of concert opera, with stage setting reduced to a minimum. An extreme of this tendency is radio opera.

Finally, opera in America, like other music forms, has absorbed many foreign elements. (Parker, *Mona;* Damrosch, *Cyrano de Bergerac;* Taylor, *The King's Henchman, Peter Ibbetson.*) Real "American Opera" has not yet emerged. Among the most prominent younger composers is Minotti (*Amalie at the Ball*). —O.O.

**operetta.** A little opera, usually of a comic or

gay text, having light and lively music. See OPERA.

**ophicleide.** See MUSICAL INSTRUMENTS.

**opisthodomos.** See HELLENIC ART.

**opposition** (Fr. *opposition*). A term in the academic theatrical dance for a means by which the body is rendered more plastic by contrast of its members arranged in asymmetrical balance. For example, the left arm and leg do not move together, but rather the left arm and the right leg. This opposition is also basis for the natural, unconscious human walk which effects a mechanical balance of weight whereby the body manages to remain in equilibrium despite transitional shifts of its center of gravity. From this essential principle, opposition further consciously enhances and emphasizes the normal elegance of the body. In sculpture of the Hellenistic and baroque periods the Italian term, *contrapposto,* expresses a static version of the same idea.

—L.K.

**optical illusion.** A term given to the phenomenon of perceiving things differently than would be normal for the visual stimulus. This may lead one to perceive one object as longer or larger than another object, when actually the two objects are the same size. It may lead one to see a pure green color as a green yellow when it is placed next to a blue green. It may lead one to see a mirage of an oasis on a desert when actually none exists.

—V.K.B.

**optical pyrometry.** *Cer.* Using experienced eye to determine temperature by color. See CERAMICS I.

**opus Alexandrinum.** See Cosmati work.

**opus sectile.** See Cosmati work.

**or.** *Her.* Gold.

**oratorio** (Ger. *Oratorium;* It. *oratorio;* Fr. *oratorio*). NATURE. The name oratorio refers to its place of origin and to its content. It derives from "oratory" which literally means chapel for prayer. Then it referred to the meetings held there by the oratorians; later to the music itself. Another equally plausible source are the oratorical acts of the medieval monasteries.

**The art form oratorio** expresses religious feeling. Therefore, it dates back in its pre-art form to the religious chants of even primitive man. Religious character remains the basic element of oratorio and we find tonal expression of this feeling in the old Hebrew temple chants and Greek Psalmody. These are the ultimate general sources. Its more immediate musical source is found in the *laudi spirituali,* the hymns of praise of the Florentine *laudisti* (13th-16th cents.), at which time representation of sacred subjects was common through Europe. Oratorio may be epic, dramatic or lyric in nature, but, unlike opera, all light or comic elements are excluded. Some early examples, however, contained these.

Oratorio, as a music form, is difficult to define since its various elements permit many combinations and classifications. Four elements should be considered; the nature of the text, whether sacred or secular; the distribution of the parts; the presence or absence of scenery and action; the relative length and scope of the work. The interrelations among these parts determine the type of oratorio. All have in common an introspective, subjective, otherworldly character, in contrast to the extrospective, objective, this-worldly character of opera. (See also mass, requiem, cantata, anthem, Passion.)

We may define oratorio as an extended composition for soli, ensemble, chorus and orchestra, based upon a biblical, liturgical or other non-secular text, without scenery or action, and intended for concert, rather than for liturgical use. The extreme difficulty in clearly defining both the content and the field of oratorio results from its basic hybrid character; it is a music form and also a religious form. There is no inherent connection between oratorio as an art form and its liturgical application, and much oratorio music is not religious in spirit. Music itself, cannot be sacred in character beyond creating an appropriate mood. (The chorale *O Haupt voll Blut und Wunden* is a secular tune.)

Sacred oratorio remains the basic and true form. When an abstract, other-worldly theme, not necessarily religious, is used, we may speak of secular oratorio (Haydn, *The Seasons*). When scenery and action are included we have sacred opera (the early oratorios, 1600; Rubinstein's *Tower of Babel*). A sacred theme, spoken and acted is a sacred drama. If the work be short, but with oratorio content, it becomes what may be called an **oratorietto,** equivalent to the sacred cantata. If any specific part of the liturgy is used as basis modifying terms may be used: Passion Oratorio; Christmas O.; Easter O.; Requiem O. If these themes are intended for liturgical use not for concert or purely musical use, the word ora-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

torio may be dropped and the works designated merely Passion, Christmas service, Mass, etc. If, further, any of the three elements be stressed, we have an epic, dramatic, or lyric oratorio. Thus extended from objectivity, stage and action determine opera; extended form, subjectivity, sacred theme but extra-church performance determine oratorio, and shorter forms determine sacred and secular cantata.

Recitative and aria, in oratorio, parallel their use in opera, the recitative being used essentially for the epic or narrative parts, and the aria for the lyric parts. All forms of recitative described under opera are used. Forms of aria also. (Aria differs from "song" chiefly in its loose repetition and elaboration of the text: the melodic outlines of both may be very similar.)

In the last analysis recitative and aria are phases of the same basic tonal representation: variations in pitch and in duration (with dynamic gradation). When neither pitch nor duration is fixed according to a pattern, we have speech (the recitative characteristic of certain forms of melodrama in which the words are actually spoken, not chanted, entirely independent of any musical background). Pitch, and metric inflection are free. At the other extreme is song, a series of definite pitch and metric patterns (phrases) closely correlated with the accompaniment. Between these extremes, all degrees of combination are found.

HISTORY. The close psychological similarity between oratorio and opera is seen in the common time origin of both; the development of monodic music about 1600. The precursors of the oratorio were the mysteries and miracle plays of the Middle Ages, and more specifically the laudi spirituali then in use. Both oratorio and opera are tonal expressions of life; oratorio, essentially serious, subjective, otherworldly, deals with the things of the spirit, religion, truth, time, mankind in the abstract, the world; opera deals with the objective aspects; heroes, love, hate, pleasure.

The earliest oratorios are associated with Filippo Neri, founder of the congregation of Oratorians at Rome, about 1600. They were religious or moralizing compositions, in extended form, with soli, chorus, orchestra, scenery and action (*azione sacra*), written by composers who also composed opera. Cavaliere's *La Rappresentazione di Anima e di Corpo* (1600) is generally considered the first oratorio, a *dramma sacro per musica*. It was essentially dramatic, based upon the *stile rappresentativo* without a clear differentiation between recitative and aria. The epic element, which used recitative for narration in the character of narrator or historicus testo, was introduced by Giacomo Carissimi (1604-1674). This rôle replaced the scenery and action. The Carissimi tradition, musically an advance over the first attempts, was carried on by Alessandro Stradella (1645-1681) a pupil of Carissimi. But lyricism, after all, remains the most natural melodic characteristic, and the next chapter in the history of oratorio finds its introduction by Alessandro Scarlatti (1659-1725), whose improvement in both recitative and aria were common to opera as well as to oratorio. The aria (developed probably by Rossi [d. 1653]) was used for lyric, emotional parts (the equivalent of song), accompanied recitative for the dramatic parts, and recitativo secco for the narrative parts. But these procedures are also characteristic of his operas.

At the time of Scarlatti oratorio had used the three elements of epic, dramatic and lyric presentation, and as texts, heroes from the testaments, allegorical personages, saints and other sacred topics. The form was scarcely distinguishable in musical content from the opera of the period.

With its introduction into Germany, by Heinrich Schütz (1585-1672) with Gabrieli forming a link, oratorio narrowed down its field to the Passions, at the same time increasing in seriousness and appropriate musical content. The metric aria of Scarlatti was discarded and a modified, expressive type of plain-chant (from the intonation of the psalms) was substituted. Later on this in turn gave way to the German Chorale, thus introducing a folk root (Sebastiani, 1622-1683). At this time, the narrator or evangelist was recited by a tenor, the part of Christ by a bass. Funke and Keiser are to be mentioned here as composers of Passion music. In the meantime the church cantata, in the hands of Buxtehude and J. C. Bach added to the serious musical forms available.

Thus far the composers of oratorio had also been composers of opera, and the two forms of music expression differed but little in musical form or substance. With Johann Sebastian Bach the separation came in striking force, and oratorio reached the highest artistic level it has ever attained. (*St. Matthew* and *St. John Passions, B minor mass.*)

(During the Middle Ages the various versions of the passion were recited with dramatic action, partly in church and partly in procession outside, leading symbolically to

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Calvary and stopping for the presentation of dramatic scenes in costumes. The modern *Passion Play* at Oberammergau is a modified continuation of this).

The entire nature of Bach's genius fitted the musical and psychological problems of oratorio. Far overshadowing his predecessors in musical inspiration and technique, and thoroughly conversant with church music in its artistic and liturgical aspects, he brought all the essential creative elements to bear on this field. Moreover, his contrapuntal command enabled him to integrate the earlier polyphony, which is appropriate to some phases of oratorio, with the later homophonic style. The successors of Bach, although they produced some creditable works, fell short of the goal (Graun, Hasse, C.P.E. Bach).

The Italian style of oratorio flourished with George Friedrich Händel (1685-1756), particularly in England where Händel lived. In his oratorios, the musical, not the religious element, predominates. They are distinctly concert conceptions, even at times theatrical (some of them were designed for scenery and action). What Bach did for the German oratorio after Schütz, Händel did for Italian oratorio (lyrically in the Messiah; epically in Israel in Egypt). The influence of the English masque is also felt, and this partly accounts for the wide and enthusiastic reception which the Händelian oratorios found in England. Händel's knowledge of opera resulted in the use of a freer recitative and aria in his oratorios. At the same time he brought the chorus to a distinctly high artistic level. His greatest work is the *Messiah* (1741), which, of all oratorios ever written, is the best known. It owes this position to the fact that it combines the two basic elements. It is neither purely concert nor liturgical material. Instead it is both: it perhaps leans more toward the Protestant liturgy than his other works. Händel also introduced the three-part division of oratorio to replace the previously used two-part division.

Since music, preceding the birth of monody, was essentially vocal, it is natural that oratorio, in the first century of its history should be developed from a vocal center. The marked development of instrumental music, however, in the 17th cent., was forced to affect all forms of music creativèness. We find this instrumental development in the works of Josef Haydn (1732-1809) both in his *Creation* and in the *Seasons*. The emphasis is placed on the musical side and although the genius of Haydn invested recitative and aria with superb artistry, it also lifted the instrumental parts, whether ritornelli or accompaniment, to higher levels than before, and this in spite of poor texts. In fact the *Seasons*, with its highly developed tonal descriptions, is on the border line of oratorio; it may well be considered an extended cantata.

With Haydn and his predecessors, all tonal elements of oratorio had been developed. The period following him did not carry either the form or the content of oratorio any further. Numerous works were written but they were of secondary stature. Conspicuous exceptions were Mendelsohn's *Saint Paul* (1836) and *Elijah* (1846), works which combine the subjective and the objective elements in the light, typical Mendelssohnian style. Both Italian and German elements have been traced in them.

Oratorio, as an original art form, has never played a major part in the music history of France, for there the performance of religious and even liturgical subjects was permitted as a form of opera, and the predominating influence of the ballet (which is naturally ill adapted to the serious content of oratorio) further restricted the field. The introduction of oratorio into France is generally attributed to M. A. Charpentier, a pupil of Carissimi, but it slumbered until much later. F. Lesueur wrote a number of short biblical oratorios which preceded the *L'Enfance du Christ* (1854) of Berlioz. This is usually considered the first French oratorio; it contains some of the finest music of this composer. Other works which have retained a prominent position are Cesar Franck's *Beatitudes* and Gounod's *Redemption*.

In no other country has the oratorio found more fertile ground than in England, although its artistic creation has been entirely in the hands of non-English composers: Händel and Mendelssohn. On the other hand, the native English anthem was a form which lent itself very readily to absorption into the oratorio and the closeness of this transition resulted in the wide and enthusiastic acceptance of the extended oratorio in England. Unfortunately, although all English composers wrote oratorios, these are of but passing interest (Arne, Wesley, Bennett). A later revival owes its impetus to Parry, Stanford, Mackenzie and Elgar (*Dream of Gerontius*).

In Germany, after Mendelssohn, numerous oratorios were composed none of which contributed significantly to its history (Rubinstein, Raff, Gade, Bruch). Liszt in his legend of Saint Elizabeth and Christus has produced works which in some respects go back to the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Gregorian intonations, in others to Mendelssohn, and in yet others to his own individuality in both choruses and recitatives.

Oratorio, as an art form of large dimensions belongs primarily to the past. Its original function as a religious expression has resulted in texts the poetic value of which is small (*Messiah*). In fact much of the best music in oratorio is not liturgical, or even sacred in character. And conversely, some of the most pious moments are not accompanied by good music. But, as a music form, the oratorio must stand independent of its religious implication. Thus its length will be limited since the range of sacred contemplation cannot possibly equal that of the opera idioms. If it develops into a realistic tone-painting of earth, heaven and hell, it will enter the realm of tone poems. Moreover, modern tonal and musical idioms are better adapted to small forms than to large ones. Subject matter and form have caused oratoria to yield to shorter types and to serious but secular contata: Brahms, *Requiem;* Berlioz, *Damnation of Faust;* Debussy, *L'Enfant Prodigue;* Pierne, *Children's Crusade;* Coleridge Taylor, *Hiawatha;* Paine, *St. Peter;* Parker, *Hora Novissima;* Strawinski, *Oedipus Rex,* and the works of Hindemith, Honneger and Hass and others. —O.O.

**orchesis** (Gr.). Used interchangeably with *nomas* by the ancient Greeks, these terms referred to the art of expressive gesture, of human movement in genera. A name that has been adopted by many dance clubs in universities and colleges throughout the United States. It was first used by the University of Wisconsin dance club, organized in 1919.

**orchestra.** (1) In ancient Greece, the place in front of the stage alloted to the chorus. (2) The place occupied by the musicians in a modern theatre. (3) The musicians themselves. (4) The instruments for which the composition is written.

**orchestration.** See instrumentation.

**orchid leaf line.** See CHINESE ARTS.

**order.** An order in architecture is a particular treatment of a column and the entablature which its supports, as to its proportions, contour and enrichment. The Greeks developed the Doric, Ionic and Corinthian orders which were used with modifications by the Romans. To these the Romans add the Tuscan and the composite orders. See capital. —O.M.S.

**ordinaries.** See HERALDRY.

**ordinary of Mass.** See Mass; MEDIAEVAL MUSIC.

**ordonnance.** Placement of the elements of a composition with regard to each other and to the whole.

**organ.** See MUSICAL INSTRUMENTS.

**organic.** An organism is a coherence of related powers which is self-sufficient, and because of this self-sufficiency stands out in relief against the world around it, as an independent thing. The adjective derived from this noun applies therefore to the state of an organism. In the larger sense of the word every work of art must be organic because it is a unified world within itself, in which all parts are so closely related to each other that they form, when united, an independent whole.

The narrower sense of the word means not only a unity of form but a representation in which the natural organic essence is self-evident. The Greek artist, e.g., always tried to make his work organic, not only in the first sense, but in such a way that the meaning of the natural organism becomes obvious. The representation of men or groups of men, of plants or groups of plants was made in such a way that the figures represented form a unity in themselves, without the need of any external completion. In doing this he started with natural organic beings which he idealized in accordance with the law of eternal images to which all things are subject (see idealism). In opposition to the southern artists, the northerners tended to works of inorganic appearance. That which they represent has need of an external fulfillment, or at least is represented in such a way that it seems to need this fulfillment in order to arrive at universal unity and balance. To do this they had to strip natural organic models of their self-sufficient character in order to make them fit their purpose.

One may compare, for instance, the antique with Germanic art; or the works of such Renaissance artists as Raphael, Leonardo, Michelangelo, with those of the artists of the Netherlands such as van Eyck, van der Goes, Rembrandt. —A.J.S.

**organistrum.** See MUSICAL INSTRUMENTS.

**organ point.** One tone sustained through independent harmonies; also called **pedal-point.**

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**organum.** (1) One of the medieval systems of harmonizing a cantus firmus by adding the octave and the 5th (or 4th); called also **diaphony.** (2) An instrument; later an organ. See MEDIEVAL MUSIC.

**Orgatron.** See Everett Orgatron.

**Oribe yaki** (Jap.). Pottery made in Owari province.

**oriental loom.** Made by fastening two poles perpendicularly in the ground to a sufficient depth, leaving above ground as much of each pole as equals in length the desired rug. This framework supports two horizontal rollers, the warp threads being wound around the upper, while the ends are fastened to the lower; the weaving is begun, and on it the rug is rolled while in process of construction. To the warp threads of fine linen or cotton the weavers tie the tufts of worsted that form the pile. This worsted, which has been dyed previously hangs over their heads in balls. When a row of knots is finished, it is pressed down to the underlying weft by a long and heavy comb with metal teeth. Then the tufts are clipped close with sheers, to make the pile. In the finer rugs there are seldom more than two or at the most three threads between every two rows of knots, but in coarser kinds there are more threads. —B.E.J.

**ORIENTAL MUSIC.** For purposes of this brief survey of an immense and highly diversified field of musical utterance, the continent of Asia will be considered the geographical orient. From Arabia, Egypt, India and China arose originally the art cultures of the Occident and its science and art of rhythmitonal expression. Oriental music employs the universal material of sound organized by rhythm, melody and tone quality. Harmony, in its specific occidental meaning and practice, is absent. But harmony—*sui generis*—is present to the oriental inner ear in a greater extent than is realized by western minds. The distinguishing characteristics of oriental music considered *en masse* are:

I. *Monophony.* For the most part the Orientals sense and create rhythmitonal beauty through the manipulation and embellishment of a single and free tonal thread. The melodic contour and pattern, plus free decorations, possible alone to monophonic music, form the basis and beauty of Asiatic tone-art. The Occident developed polyphony; the Orient developed the beauty and expressiveness of monophony, an aesthetic practice and viewpoint carried out in much of its visual arts and crafts. The folk and art songs of India reveal a loveliness and distinction of tone line that is unmatched in western music. This is true in part of the enduring body of Chinese and Japanese folk songs. Since oriental music submits to the same general classifications as does occidental, the spontaneous folk utterances can easily be contrasted with ritual music and conventionalized classics. Western polyphony is approximated in the Oriental's use of a variety of percussion and plucked string instruments as a simple-to-complex rhythmic background to the horizontally flowing melodic line, thus combining the physically rhythmic with the melodically aesthetic in emotional conflict. His conception and application of the rhythmic principle are extensive and subtle; measured, accented meters give bisymmetry, and measurable flowing rhythms asymmetry to his lyrical and dance forms. The rhythms in singing poetry and free verse follow rules of his prosody and the metre of national poetry. They are based on vowel lengths, not upon stress as in western song; the fixed unit in such a free song or chant being a section or group of bars which are not necessarily alike. Three rules are broadly applicable to all oriental songs of this free class: the rhythm must follow (a) the words; (b) the melody; (c) the rhythm deciding the close of sentences. The Oriental is not hampered by bar lines or chordal harmony; is free when freedom is desired; is a consummate master of a wide range of irregular rhythms (i.e. 5, 7, 11 beats to the unit), with syncopated cross rhythm in threes or fours. The interrelation of rhythmic and tonal movement, and linear relation of tones have an intimate bearing on oriental folk and classical forms.

II. *Use of the pentatonic scale common to most folk utterance.* Oriental folk music, particularly that of China and Japan, is reminiscent of Celtic folk music since the pentatonic tone-series is common to both. The ancient nomenclature of the Chinese pentatonic series reveals the close relationship existing between the State and its music. Taken in ascending order from F it is called **Emperor, Prime Minister, Loyal Subjects, Affairs of State, Mirror of the World.**

*Employment of intervals smaller than half-step.* Generations of conscious or unconscious manipulation and modification of melodic intervals in a musical system unfettered by fixed harmonic relationships tends to the distintegration of even the smallest intervals ac-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

cepted by the Occidental as practicable. These microtonal intervals are used largely in the tonal embellishments but when heard with understanding the elaborate decorative "graces" become a structural factor in oriental improvisation and composition. Orientals have divided the 12-tone octave into fractional steps; the Arab, for example, recognizes 24 to 26 intervals within the octave. The Hindoos have further refined these intervals in theory and practice, hence a large number of traditional modes (called ragas in India) are available to the Indian musician-poet. Attributing definite ethical, social, or temporal significance to a single tone, and to a modal series is highly characteristic of Orientals, for music, qua music, did not attain its complete independence in either the classical or modern epoch. World War II will necessarily hasten its rise into that status.

III. *Melody.* Melody is the source, life and destiny of oriental song. Its fluid rhythms, illusive and prismatic pitch intonations and instrumental tone-colors, when inter-fused, or when associated with words, reveal a new facet of beauty to western ears. A constant connecting of tone with tone through portamento, gives to Far Eastern song and instrumental solo a continuity of sound unknown in western music, demonstrating the importance in oriental music of the interval over the single note. The oriental singer is also a poet. His art is impersonal, reflecting emotions and experiences deeper than those of any single individual.

IV. *Musical Instruments.* The understanding and evaluation of Oriental music demands a knowledge of its ritual and secular instruments. Their types, limitations and capabilities have to a marked degree created their musical aesthetic and technical practices (see MUSICAL INSTRUMENTS).

V. *Symbolism.* Ancient oriental culture and civilizations have developed fixed and ideal conventions in spatial and temporal arts. Their ritualistic music has become in large measure an art of reviving strong associations and intensifying desired moods. Melodies and tone qualities are appreciated, not necessarily for their own aesthetic values and self-sufficient beauty, but as symbols of ideas, the elements, and spiritual states of inner experience. The Oriental's philosophic mind synthesizes his arts, seeking, and, to his satisfaction, attaining an at-one-ment with the beauty and meaning of life itself. This aesthetic philosophy penetrates his traditional and serious music and rewards him with a clearer perception of and keener spiritual participation in the terrestrial and celestial drama of human life. **Oriental perspective.** See PERSPECTIVE.

**oriental rug dyes.** *Cochineal* (coccuscacti) is the product of an insect which lives on a species of cactus. It yields a red dye. *Indigo* yields the deep blue dye. When the Indian indigo plant (indigofera tinctoria) is in flower, it contains the largest quantity of coloring matter. *Kermes* (Oriental origin means worm, Sanskrit form is *krmi.* In ancient Iranian it is known as *kerema* and in Lithuanian as *kirmis.* Bible furnishes oldest evidence of existence of this dye, uses Hebrew name *tola* or *tolaat,* meaning worm. Greeks and Romans believed it to be *kokkos* (berry). Crimson, *cramoisi* (French), and *Karmin* (German) are derived from same root). Grains are dried bodies of female of a species of shield-louse. Insects attach themselves firmly to branches and leaves by means of their jaws and remain motionless, gradually swelling to a round shape which explains why Greeks believed it to be a berry. Kermes is more durable than cochineal. *Madder* (q.v.) is a common dye used for red. *Saffron* yellow is often produced from Persian berries, turmeric, saffron, and sumac. Greens are obtained from various sources. The fruit of several buckthorns, or the Persian berries gives also greens and brilliant yellows. Most of the greens however are produced by the combination of indigo with yellow. Synthetic dyes for carpets were not known to the East until 1865. —B.E.J.

**oriental rugs, doctoring of.** A method used to paint the pile with dyes which have been dissolved in alcohol and painted on to the rug with a brush. It is done to correct inequalities and imperfections in original coloring or to give the customer the exact color desired. Color applied in this way is not permanent and can be usually detected by opening the pile. —B.E.J.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**Oriental rugs, kinds of.** *Afghan, Bakshi, Baku, Bectash,* Mohammendan, *Beluchistan, Bergama, Bokhara,* Chinese, Dasmascus, Dragon rug, *Feraghan, Ghiordes,* Hearth rug, *Herat,* Holbein rug, so-called, Indo-Persian, *Jushagan, Kazak, Khorossan, Kilim, Kis Ghiordes, Koula, Kuba, Kula, Lâdik, Makri, Mudjur, Oushak,* Polonaise, prayer rugs, Rhodian, Samakand, *Saraband, Shiraz, Soumak,* Syrian. See *Catalogue of Oriental Rugs in the Collection of James F. Ballard,* J. Arthur McLean and Dorothy Blair, Indianapolis, 1924. —J.A.M.

**Oriental rugs, main elements of.** Border, field, guard lines, guard stripes, knots, Sehna and Ghiordes, panel, spandrels. See *Catalogue of the Oriental Rugs in the Collection of James F. Ballard,* J. Arthur McLean and Dorothy Blair, Indianapolis, 1924. —J.A.M.

**Oriental rugs, methods of identifying.** No one can determine with reasonable certainty the character and origin of an Oriental rug unless he understands the character and origin of the 5 or 6 groups of Asiatic rugs. Identify it by the manner in which it is made instead of by its appearance. The student will be assisted by a study of the following rules.

*Rule I*: (a) Caucasian and Turkoman designs are almost invariably geometric. (b) Turkish designs are frequently of floral and highly decorative character, detached motifs. (c) Persian and Indian designs are usually complete compositions. (d) Samarkand and Chinese designs employ detached motifs, animal, floral and geometric.

*Rule II*: By an analysis of the technique of a rug it will be found that the only rugs that are tied with the Senna knot are: Fereghan, Kirman, Khorassan, Ispahan, Seena, Bokhara, Khiva, Afghanistan, Beluchistan, Yomud, Beshire, Semarakand, and some Chinese. All other rugs are tied with the Turkish or Ghiordes knot.

*Rule III*: The pile of a rug is, of course, wool, but the web, consisting of the warp and the filling upon which the knots are tied, is a guide often to the character of a rug. Thus, most of the Persian rugs have cotton warp and weft; most of the Turkish Kurdistan and Turkoman have wool warp and weft. Caucasian rugs follow no rule; some being of wool warp and cotton filling. In the large carpet size rugs we distinguish grades very quickly, cotton being commonly used. The Turkish Oushake, however, have wool warp and wool filling. So also the Demirdji, modern Kulahs, Akhissars, Caesarians and Kirshehrs—all Turkish. Where the warp and filling are cotton, the rugs are Persian, with the exception of the Khorassan, which employs wool in the filling. The Samarkands may have wool or cotton; so also the Chinese.

*Rule IV*: Rugs showing at the ends a wide web instead of mere fringe, the web being sometimes plain and sometimes embroidered are: Bergamo, Afghan, Makri, Beshire, Beluchistan, Yomud, Bokhara, Shiraz, Niris, Ladik.

*Rule V*: It is a safe rule that Persian and Mosul rugs have overcast sides and Turkish, Turkoman, Turkestan and in most cases the Caucasian pieces have selvaged sides. Care should be taken, however, in determining characteristics by the side finish, that you be not deceived by an applied edge, sewed upon the rug as simply a repair job, where the original edge is frayed or ragged.

*Rule VI*: Where a rug is exceedingly fine, as indicated by the back, it may be any of the following, which contain one hundred or more knots to the square inch: Ispahan, Ladik, Ghiordes, Kashan, Senna, Kabistan, Antique Kulah, Kirman, Saruk, Tabriz, Kermanshah, Daghestan, Bokhara, Chichi. These are all, naturally, short pile rugs.

*Rule VII*: In the texture of the sides of a rug there are also distinguishing marks. Goat hair is conspicuous in the heavy selvage of the Yuruks and Beluchistans; parti-colored yarns in the sides of the Shiraz; fine silken cord is used on the Saruks; parti-colored selvage is used on the Yomuds and Genghis.

With the following rugs no rule applies: Caucasian, Shirvan, Kabistan, Leshgian, Turkish, Oushak, Kaba-Karaman, Modern Kulah, Demirdji modern, Ghiordes modern, Akhissar, Karadagh. —B.E.J.

**original boards.** *Book.* The boards or covers or other wrappers in which the book was published.

**Ormazd.** In Zoroastrianism, the chief of all the gods, the supreme deity, guardian of mankind, source of all good.

**ormolu.** A variety of brass made to imitate gold in appearance, much used in France in the 18th and early 19th cents. as a decorative accessory to furniture, etc. See metalwork.

**ornament** (L. *ornare,* to adorn) is an additional element to an otherwise merely structural form. This form may represent a building, a piece of furniture, a weapon, an in-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

strument, etc., created in three dimensions; a lace, a fabric, a book cover or the written or printed page or a book, or even a single initial, in only two dimensions. Thus the ornament always means an accessory which may be added or taken away without changing the essential character of the ornamented subject.

Since the ornament is always something added—either as decoration of an architecural structure or as an embellishment of potteries or extiles; e.g., it follows and expresses the "style" of a certain period as accompaniment to the respective larger form, only that this ornament is not restricted by any functional needs or considerations. Therefore, changes in ornamentation usually follow each other more quickly than the stylistic changes which are expressed in the decorated works proper. Thus the knowledge of the history and development of ornament renders the best means for an exact dating of works of fine and applied arts.

Even the fact that in certain periods the form of the ornament itself is influenced by the function of the bearer of it or by the material in which it is executed, or by the technique in which it is applied, does not change the typical additive character of any ornament. The most materialistic conception of an ornament, however, can never reduce the meaning of the ornament as such to any utilitarian tendency of design.

Without attempting either to enumerate all the different ornaments throughout the ages or to give the history of the development of each single ornamental form (see arabesque, band ornament, echinus, grotesque, maeander, rocaille, etc.) it must be stated that some characteristic principles of their origin repeat themselves and can be followed through all the stylistic periods.

Generally speaking, we can distinguish between two main groups in ornamentation: geometrical-abstract forms on the one hand and naturalistic-vegetable forms on the other. This does not contradict the fact that very often originally geometrically conceived forms develop into naturalistic formations, and that vice-versa sometimes the abstract expression becomes less outspoken by leaning on similar naturalistic forms.

Examples for the geometrical-abstract principle of ornamentation can be found in most primitive civilizations. There the magic character supersedes the decorative tendency of the respective pattern (totemism). In some civilizations of the Near and Middle East within certain periods (in the archaic Greek culture, in the peasants' art of Europe, etc.) the geometrically abstract principle is dominant. Motifs developed from the technique of weaving, such as knots, crossing threads, etc., elements from handicraft like the so-called *Beschlagwerk* (mounting) are taken over and translated into geometrized forms and thus applied, for instance, on pottery or engraved into metal. Sometimes, even three-dimensional motifs are translated into two-dimensional colored abstractions.

The naturalistic principle in ornamentation can be found to some extent as early as in the drawings of the cavement. In Egyptian civilization, and esp. in the realm of Cretan-Minoan culture, naturalistic motifs occur very frequently, and in the development from the archaic Greek period to the climax of Greek art in the 4th cent. and the following Hellenistic period, naturalistic ornamental forms flourish more and more, gradually superseding the geometric tendencies.

Throughout history, the development oscillates between these two extremes: geometrical-abstract and naturalistic-vegetable. In the decorations from the early Christian (q.v.) era to the Ottonian (q.v.) epoch the frequently used naturalistic motifs representing Christian symbols (grapes, fish, etc.) should not be misinterpreted as original ornamentation. They represent merely abbreviated depictions. The later medieval centuries develop increasingly a naturalistic treasure of ornamental forms (on capitals of pillars and columns, borders, friezes, etc.) which eventually leads to the rich naturalistic Renaissance ornamentation, a logical outgrowth of the revival of ancient forms. Since then the whole "vocabulary", so to speak, of "motifs" is fixed and relatively limited. Only occasionally a geometrical motif slips in like, e.g., in some geometrical Chinese ornaments in the 18th cent., or during the Classical Revival, archaic Greek formations. Two ornamental forms, however, can really be called creations of Renaissance and Baroque times: the scrollwork in the 16th cent. and the rocaille in the 18th cent.

The variations of ornamentation mirror most exactly the tastes and preferences of the respective countries, nations, and periods. Thus to follow up the change of a certain individual motif from its first appearance through all its stages of migration in the geographical and temporal sense would give the clearest insight of the differences in the visual and artistic conception of the respective countries and periods. See Owen Jones, *The Grammar of Ornament*, London, 1865; G. Hirth, *Der Formenschatz*, Munich, 1879 ff; O. Reynard, *Catalogue d'*

**ornament engraving.** While in our days photographs of former artistic expressions can be used for stimulating artisans and craftsmen in creating patterns for applied art, former times had to rely on models brought down by means of graphic art which could be reproduced.

The 15th cent. invented the so-called ornament engraving to fulfill this purpose of being model. Before that time, inventor and executor of a work of art were mostly the same person, so they did not need this link. Now woodcarvings and engravings, helped very much by the invention of printing, did their part in spreading new forms. Thus, architects, sculptors, and painters became not only leaders in their respective fields, but by the means of the ornament engraving (in the beginning mainly woodcarvings) their inventions or details of them were carried on for further use by later generations and in other fields of art.

This short explanation shows already that the word "ornament engraving" covers much more than only engravings of ornaments. We use this term for engraved models, published in single sheets or in whole series, determined for all kind of gold—and silversmith's work, for carpenters, panel painters, embroideries, details of doors and windows, pieces of furniture, iron work, etc. We know innumerable engravers who by purpose did their engravings only for model's sake. Ornament engraving was especially wide spread nearly during all the periods from the 16th to the 17th cent. in Italy (Zoan Andrea, Agostino Veneziano, Enea Vico, Agostino Mitelli, Bernardino Radi, Stefano della Bella, Guarino Guarini, Filippo Passarini, etc.), Germany (Hans Sebald Beham, Heinrich Aldegrever, Peter Flettner, Virgil Solis, Lucas Kilian, Christoph Jamnitzer, J. C. Bodenehr, Paul Decker, Johann Jacob Schübler, Hoppenhaupt, Jeremias Wachsmuth, Johann Esaias Nilson, etc.) and France (Jacques Androuet Ducerceau, Etienne Delaune, Jean Lepautre, Jean Vauquer, Jean Bérain, Daniel Marot, Claude Gillot, Jean Pillement, Nicolas Pineau, Charles Huquier, Jean François Forty). In the Netherlands, ornament engravings excelled in the 16th and 17th cents. (Cornelis Bos, Johannes Vredeman de Vries, Adriaen Collaert, Peter Quentel, Artus Quellin, Philps Vingboons), while England had its highest development in the 18th cent. (Robert and James Adam, Thomas Chippendale, William and John Halfpenny, George Heppelwhite, Thomas Sheraton).

It needs no stressing that for ornament engravings no specific style can be typical; on the contrary, since they flourished through three centuries during which time they gave stimulation to artisans, they always showed clearly the typical stylistic elements of each respective artistic period. See O. Reynard, *Catalogue d'ornements dessinés et gravés,* Paris, 1846; D. Guilmard, *Les maîtres ornemanistes,* Paris, 1880; *Katalog der Berliner Ornamentstich-Sammlung,* Berlin, 1935; Peter Jessen, *Der Ornamentstich,* Berlin, 1920; Rudolph Berliner, *Ornamentale Vorlageblätter,* Leipzig, 1925-1926; Fiske Kimball, "Sources and Evolution of the Arabesque of Berain", in *The Art Bulletin,* vol. XXII, No. 4, 1941. —L.P.E.

**ornamentation, architectural.** The embellishment of architectural or structural forms which is intended to enhance the appearance.

**ornamentation, tongue.** Any ornamentation in which a form resembling a tongue is used as a motif, such as the Greek egg and tongue molding. —O.M.S.

**Orpheus.** The greatest of Greek musicians, famous for his tragic attempt to bring his wife, Eurydice, back from Hades, and the founder of the Orphic Mysteries, which promised worshippers a blessed immortality. In ancient art he was often pictured on vase paintings. Post classical sculptors who have represented him include Crawford, Rodin, Gregory, Stewart, and Carl Milles. —W.R.A.

**Orphism.** Abtstract style founded in Paris in 1912, named by Apollinaire, and represented by Delaunay and Kupka. By "Orphism", Apollinaire meant an art of pure "musical" lyricism of color. See FRENCH ART. —L.D.L.

**orpiment.** Known also as King's yellow, this painter's pigment was once widely used in the Far East and in Europe. It is mentioned by classical writers and has been identified on many illuminated manuscripts of the Middle Ages and the Renaissance. It is closely related to the orange-colored realgar and is a natural, crystalline, yellow sulphide

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

of arsenic, occurring as a deposit in Hungary, Macedonia, Asia Minor, and variously in Central Asia. —G.L.S.

**orthographic projection** (Gr. *'orthos,* straight, and *graphein,* to write). A projection in which the projecting lines are perpendicular to the plane of projection. In architectural drawing it is a drawing where each face of an object is seen in side elevation. The order of such drawing is prescribed as back, left, front, right; and then, above the front is the top; and below the front is the bottom. —V.K.B.

**oscillogram.** See harmonic analysis.

**Osiris.** *Egypt. Relig.* The god of the underworld and judge of the dead; brother and husband of Isis.

**Otsu school** (Jap.). A crude style of painting; the beginning of the *Ukiyo-e* school (q.v.).

**Ottoman art.** See ISLAMIC ART.

**Ottonian art.** So-called from the German emperor Otto the Great of the house of Saxony, 936-973, or 963-973, respectively But it includes almost all the reigns of the German Saxon kings who ruled from 919 to 1024. The high point of the Ottonian epoch was around the year 1000. The reign of Henry I (919-936) and even part of the reign of Otto I, show elements of the style of the late Carolingian period rather than the Ottonian epoch, while under Henry II (1002-1024), there were already noticeable signs of the transition into the Salian style.

Ottonian art developed a true German national style and is noted for its extremely fruitful activity.

In the field of architecture the ground plans were designed and the foundations stones laid for many important cathedrals, such as the Cathedral of Mainz in 975, the Cathedral of Worms in 996, the Cathedral of St. Peter in Minden in 952, the Cathedral of Essen and the Cathedral of Augsburg (1915). The first building of the Ottonian epoch that still stands is St. Cyriacus in Gernode. The only large remaining building which shows, in spite of later changes, the character of an Ottonian interior is St. Michael in Hildesheim (begun after 1001 by Bishop Bernward).

In regard to painting the most important school was located on the island of **Reichenau** in Lake Constance. This school included several distinct groups. The oldest group was the **Eburnant,** which combined the late Carolingian with the Ottonian style. The **Ruodprecht group** was named after the writer of the Egbert Psalter, written between 984 and 993 at the order of the Archbishop of Trier. The **Liuthar group** was named after Liuthar who wrote the Evangeliar of Otto III, now in the Cathedral of Aix la Chapelle. The style of this group was remarkable for its dynamic and dramatic expression. Works by the same group are, among others, the Evangeliar of Otto III of the Cathedral of Bamberg (now in Munich), and the Bamberg Apocalypse. Perhaps the most important work of the whole Reichenau school was the Egbert Codex done by the brothers Kerald and Heribert at the order of the Archbishop of Trier. Besides the workshops of Reichenau there were the important and well known schools of painting of Echternach, Mainz, Cologne, Hildesheim, and Regensburg. The best known of these are the workshops of Cologne, Regensburg, and Hildesheim.

In sculpture they were especially occupied with reliefs made from ivory, metal, stone and wood. The oldest ivory reliefs of the time of Henry II still showed the characteristics of the late Carolingian style. There is the ivory cover of the famous Echternach Codex Aureus done in the famous Echternach workshop about 990. From the Hildesheim workshop came the two halves of the bronze door of St. Michael's Church created under Bishop Bernward in 1015. From the same workshop, but done by a different master, came the so-called Easter Column. 3.79m high, and 0.58m in diameter, covered with scenes from the life of Christ. Other important sculptures of the same time are the antependium of the Cathedral of Aix la Chapelle, the bronze door at the south entrance of the Cathedral of Augsburg, the antependium of Henry II of the Cathedral of Basle (now in the Cluny Museum in Paris), the gold statue of the Virgin and Child in the Cathedral of Essen. Made a little later but still belonging to the Ottonian epoch stylistically is the wooden carved door of St. Maria im Kapitol in Cologne.

Among the works of applied art are the crown of the German emperors, the most famous treasure of the Middle Ages which was remade under Konrad II (1024-1026), the portable altar of St. Andreas, done under Archbishop Egbert of Trier (975-993), and several enamelled crucifixes of Mathilde, the niece of Otto II, in the Cathedral of Essen.

**overblow.** To blow through the tube in wind instruments in such a manner as to produce harmonics. See ACOUSTICS.

**overcast, oversewn.** *Book.* A variety of forms of overcasting. The principle of all forms is that the stitch goes through the side of the section or sheaf of leaves closed flat, taken out at the other side and around the back before being re-inserted. Sometimes ordinary machine sewing—like a hem on a garment—is described as overcasting. —H.E.S.

**overglaze painting.** *Cer.* Decoration applied directly to the glaze is called overglaze painting. See CERAMICS I.

**over-grazing.** See CIVIC PLANNING.

**overpass.** See CIVIC PLANNING.

**overs.** *Book.* Complete copies or sheets over and above the number ordered from the printer; i.e., an edition of 1,000 usually numbers 1,006. Sometimes depends upon the size of the paper and its cutting. —H.E.S.

**overtone.** See harmonic analysis; ACOUSTICS.

**overture.** Compositions called overtures (Fr. *ouverture;* Ger. *Ouvertüre, Vorspiel, Einleitung*) are in most cases introductions to operas, oratorios, cantatas, etc., or the first of a collective group of movements such as a suite (see J. S. Bach's *Orchestral Suites*) The earliest operas have commonly a short introduction, sometimes called **sinfonia** or **toccata.** The "sinfonia avanti l'opera" developed into two principal forms, the French overture, a slow-fast-slow movement, of which Lully is believed to have been the inventor, and the Italian overture, a fast-slow-fast movement, associated wtih the name of A. Scarlatti.

The French form began characteristically with a pompous, slow, dotted rhythm, the *stile alla francese,* to which succeeded a brisk fugal passage, the whole terminated either by a return to the original slow passage or in some dance rhythm. This form was used by many composers, including Händel (see the overture to *The Messiah*) and J. S. Bach (see the four *Suites for Orchestra,* the *Partita in D major,* etc.).

The Italian overture was more suggestive than the French in influencing later forms, especially the symphony, which quite generally follows in its several movements the order of fast, slow, fast.

Before Gluck the opera overture had little, if any, direct bearing on the drama which followed, though in church music the character of the introductory instrumental passages is frequently appropriate to the remainder of the piece (see J. S. Bach's church cantatas and *St. Matthew Passion*). "The overture", wrote Gluck in his Preface to *Alceste,* "ought to apprize the spectator of the action to be represented and, so to speak, constitute itself the argument". Gluck himself failed to make this connection in all cases between overture and subsequent action, but he stated an ideal generally accepted by subsequent composers, and in his *Alceste* and *Iphegénie en Tauride* he did make, in overtures, clear references to the drama. Among the notable dramatic works in which may be found an immediate relevance of overture to drama are Mozart's overtures to *Don Giovanni, The Magic Flute, The Marriage of Figaro,* Beethoven's overtures to *Fidelio,* Weber's overtures to *Euryanthe* and *Der Freischütz,* and all of Wagner' overtures (or, as they are in some cases called *Vorspiele* or *Einleitungen*).

Many forms of introduction or overture to opera and other dramatic works are to be

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

found in the literature from Mozart to the present. Certain types may be distinguished: (1) The prelude of varying lengths, suggesting the scene or the action to follow. Wagner employs this type of prelude (*Vorspiel*) in *Das Rheingold, Die Götterdämmerung, Tristan und Isolde.* Verdi introduces both his *Otello* and *Falstaff* by short passages. Richard Strauss is similarly brief in the introduction to *Salomé* (in *Elektra* he dispenses entirely with an introduction) and uses a short, though highly suggestive introduction to *Der Rosenkavalier.* Puccini and Debussy are also brief in coming to the opening curtain. (2) The potpourri of melodies later to appear in the action. Such stringing together of melodies is found chiefly in light operas, though the overture to Rossini's *William Tell,* while intended as a tone painting of the scene of the tragedy, is little more than a series of tuneful episodes. (3) The sonata-form overture, employing the essential principles of the movement which is commonly the first in the cyclic sonata, symphony, quartet, etc. With modifications and adaptation to dramatic purposes, this form of overture is found in Mozart (*Marriage of Figaro*), Beethoven (*Leonora*), and Wagner (*Die Meistersinger*).

These categories are by no means inclusive of all overtures. Many notable examples, such as the Overture to *The Magic Flute,* which is fugal with an introduction and episodes, fall outside these classifications.

The term overture has been used (esp. in the 19th cent.) for works which were not intended as introductions to operas, oratories, or cantatas. At times even symphonies have been so called. Certain one-movement works, commonly in sonata-form, written as preludes to plays or simply as musical counterparts of characters, scenes, or dramas and intended for concert performance, are known as **concert overtures.** Among the notable examples of such overtures are Beethoven's *Weihe des Hauses* and *Coriolan,* Mendelssohn's *Midsummer Night's Dream* and *Fingal's Cave,* Schumann's *Manfred,* Tchaikovsky's *Romeo and Juliet* (called a fantasy overture).

—R.D.W.

**ovolo.** A classical moulding of single convex curve in a form approximating an oval or half ellipse; often ornamented with the egg and dart pattern.

**oxidizing flame.** *Cer.* Flame in which complete combustion occurs. See CERAMICS I.

**Oxyrhynchus hymn.** A Christian hymn in Greek notation from the 3rd cent. found at Oxyrhynchus, Egypt in 1922. This hymn is the only extant example illustrating the transitional period from the ancient Greek music to early Christian music. See no. 1786, *Oxyrhynchus papyri,* Part XV, eds. B. P. Grenfell and A. S. Hunt, transcribed by H. Stuart Jones, 1922. —V.A.

**padded leather.** *Book.* Leather bindings with blotting paper, cotton wool, or other padding between the leather and the boards.

**pagoda** (Port.). A towerlike building in a Buddhist compound. Inasmuch as it is often non-functional, and the highest building in the compound, it serves somewhat the same purpose as the spire of a cathedral; a visual focal point. —J.A.M.

**p'ai lou** (Ch.). An architectural form of gateway commemorating a virtuous deed or person. See CHINESE ARTS.

**painted enamel.** See ENAMELLING ON METAL.

**painterly.** (The term has entered our vocabulary through Heinrich Woelfflin's *Kunstgeschichtliche Grundbegriffe* [Munich, 1915, Eng. trans., *Principles of Art History,* 1932], in which he uses it in contrast to "linear". According to this theory, which was drawn from a small sector of art history, there is a genetic law of human optics whereas early styles must mature into painterly styles.) While the "linear" stresses the expression of forms or ideas by lines with the main accent on the contour, the "painterly" emphasizes the rendition of masses and their relation to light appearing as color, tone, shade or shadow. It is called "painterly" because it indicates more the painter's handling of color and brush than the "linear", which refers to the act of drawing and not of coloring. The painterly form is achieved by a dense network of lines (which makes it evident that lines as such do not make a style "linear") or by merely alluding unevenly rendered lines as we find those two elements in Rembrandt's etchings, or by blotches of color, blended together with their neighboring colors, which are descriptive of light sensitive surfaces as seen in Titian's later paintings.

While the linear implies usually a definite statement as to the structure of the objects and eliminates the element of change, the painterly, speaking in terms of masses, surfaces, light and shadow, tends toward an emphasis of the casual circumstances of presentation, such as illumination, motion, mood, etc. The painterly draws more directly from visual experiences under a given condition than does the linear. It becomes the ideal expression for groups, nations or individuals whose eye sensitiveness is less controlled by intellectual abstractions. This more sensuous quality of the painterly style may either be put into the service of realistic art (cf. Velasquez or French impressionism) or be used sybolically as transcendental light (cf. Rembrandt, Greco, Redon).

The term may be applied in a derivative sense to sculpture and architecture as well. Thus, the Hellenistic sculpture, the statues of Bernini, the architecture of the German Baroque, the marble of Rodin, can be termed "painterly".

By no means should painterly be confused with "picturesque" although in the final effect they may coincide. The "picturesque" refers to an arrangement of nature or art in which we can project the mood of the romantic, the extraordinary, the contrasting, while "painterly" merely describes a way of rendering visual data. For the same reason it is not identical with "pictorial" which, according to the Oxford Dictionary, means "consisting of, expressed in, or of the nature of a picture or pictures".

The interesting literature of the 18th cent. pertaining to this problem will be found under "picturesque" (q.v.).

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

The stress on the painterly function of color and line appears in art theory much more rarely than the emphasis on design (*dessin, dissegno, Zeichnung*) as the basis of art. This is due to the prevailing intellectualism of art theoreticians on the one side and to the beginning of art theory in the era of the Renaissance with its outspoken linearism on the other. Even the art theory of the Baroque era emphasized the linear much more than it was practiced in actual creation. The "painterly" comes strongly forward in the essays of Sir Josuah Reynolds, preceded by the 18th cent. theorists' discussion on the related "picturesque", and in the discussions of the French Romantic and Impressionist school (cf. Delacroix, Gautier, Baudelaire, Zola, Signac). Recently, with a "plasticity craze" (L. Venturi) in art criticism, the consideration of the painterly in theory and practice has receded again. See Heinrich Woelfflin, *Kunstgeschichtliche Grundbegriffe,* Munich, 1915, 2nd ed., 1929 (Eng. trans., *Principles of Art History,* 1932); August Schmarsow, *Zur Frage nach dem Malerischen,* Leipzig, 1896. —A.N.

PAINTING. *I. Painting materials and techniques.* To understand the achievements or effects, as well as the limitations, of painting, it is necessary to remember that every painting is an object made by a man at a particular date. The artist's effects may describe him as progressive or reactionary; but he cannot exceed his materials. There is even some doubt if he can think ahead of the materials which he already possesses. This viewpoint is most ably presented by Charles Marriott who says, "art is primarily the characteristic use of materials, and the representation of nature and the direct action of design are both incidental to that. . . ."

The three basic materials are a colored powder, a liquid adhesive and a support. The colored powder may be an inorganic (mineral) or an organic (animal, vegetable) substance. The fluid in the adhesive will be water or oil, or may be an emulsion which is a combination of the two. The support may be fabric, paper, papyrus, leather, wood, artificial board, plaster, stone, metal or glass. The accessories of the painter, such as brush, pen, palette, palette knife, model, anatomical figure, air-brush, varnish, stretcher and frame, are inconstant materials used only at certain times. Their variability and use is relatable to the effects which the artist achieves; their *availability* is intimately related to the effect.

The present most popular method of painting is in oil; the finely grained pigment is in this case ground in linseed or poppy oil; the method was made practicable for the "fine arts" in the 14th cent., was quickly adopted both in the North and in Italy.

The next most popular method, at least till recently, is watercolor; tempera painting may be replacing it. In the former, gum arabic is usually the adhesive; in the latter, yolk of egg is customarily the binder. Italians of the 14th and 15th cents. favored tempera. Fresco, the painting on wet lime, a most arduous procedure, is likewise experiencing efforts at revival. The method of the Greeks and Romans, use of beeswax as a binder, is seldom attempted in its pure form; it did not prove durable.

The Marriott thesis, to be significant, must presume that the practicability of available materials will ultimately determine their popularity. Yet in the application of this judgment one must consider materials which the artist does not use directly. For instance, the improvement of the camera, as by its ability to register color accurately, may result in a diminished use of oil as a painting medium for artists—inasmuch as the oil technique is especially adapted to achieving the camera's effects. In this case the camera will have partially supplanted oil painting. This very process seems, indeed, to be going on today; tempera has increased in popularity at the expense both of watercolor and of oil.

Applying the thesis still further, one may judge what is apt to happen to the current attempts to revive fresco. One will note that the revival was instituted in Mexico where the thick masonry wall is an ideal support. In Western countries generally such structure is rapidly becoming outmoded. The effects peculiar to fresco would seem, accordingly, to be dated.

TECHNIQUES. More variable even than the materials which the artist may use, are the techniques by which he applies color to the support. Each technique is but primarily dependent, but most emphatically is dependent, upon the materials selected. For instance, a limp sable brush cannot possibly simulate the rugged effects of a stiff bristle brush; likewise, oil painting cannot achieve the color intensity of tempera; tempera, because it dries so quickly, cannot be worked into the tonal modulations of which oil is capable.

To illustrate. The especial color effects

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

in the Italian painter Uccello could only be achieved by a glazing of pigments, as his red over gold—a procedure which oil made possible. Or again, in modern times, the "pointillist" tapping with the stiff brush replaced the traditional stroking of the brush in such men as Signac, ostensibly because they wished an impersonal technique which would be analogous to, and would simulate the effects of, modern science. Yet for the pointillist technique to become popular, and to be utilized as an element in the more complex techniques of 20th cent. men, it was necessary not only that the bristle brush be invented, but that it be produced in quantity and cheaply; for nothing wears down and distorts the brush like the tapping technique.

No two artists will, however, handle watercolor, tempera or oil paint in the same way. There are, to be sure, certain general consistencies of time and place. The English, perhaps because they were the first to popularize watercolor, retain the most rigid concept of how it should be used. In Flanders, similarly, oil painting helped quickly to formulate a linear (q.v.) painting style which itself persisted long after this medium had obviously looser and broader technical possibilities. The individual artist therefore chooses his materials, then arrives at his technique; his choice and the development of his craft are dependent upon the time and locality in which he lives, the commercial availability of certain pigments, brushes, supports, the purpose he is conscious of when he paints, his intelligence, the nature of his schooling, and the character of his own temperament.

With so many factors involved, the degrees of what we term proficiency or excellence in a work of art are, of course, tremendous. But a consideration of the basic conditions for the making of every work of art revealed this to us: the object is always made at a particular time; the relationship of the object to the time in which it was made becomes a constant, even if a complex, factor which we can study.

MODERN MATERIALS AND TECHNIQUES. One of the decisive factors which in the 19th cent. conditioned the development of art—the use of materials and techniques included—was the discovery of the past by the painter. The consciousness of past styles was before this very slight; the emergence of art history from its archeological phase, and the printing of cheap reproductions, were partly responsible for the change; quickly the painter learned to distinguish authentic ancient sculpture, the Renaissance and Dutch painters, the remote and the near past. The establishment of public museums even permitted him to see the originals. One of the first results was revivalist painting. Artists like David, imbued with the ideal of a French regime founded upon Athenian principles, sought to weld a contemporary painting style from the fragments of classical sculpture with which they were familiar. The effort was abortive because the revivalists violated in several respects the time-object consistency: they often borrowed from marble Roman copies of bronze Greek sculptures, and they sought to capture in their oil medium an expression and a pictorial organization which had been formulated in carved relief. The result is the artifice of the box-like space in which the stilted actors strut and gesture in complete indifference to each other. Moreover, following the example of extant antique reliefs, from which the hand of time had picked off the pigment, the neo-classicists held color in contempt.

Only gradually did artists achieve a consciousness of the old techniques in relationship to the old expressions. This awareness resulted in the really great discovery of the 19th cent.; viz., that the past was the most effective of all teachers but that she must never be imitated.

In its negative aspects the result is a constant and aggravating search for novelties—negative because a style cannot ever really be invented. Positively, the achievement is a fixation upon qualities which have most permanence through time. The desire to be an innovator, yet to produce work which will never cease to please man, is the exclusive dual ambition of the modern artist.

One of the most positive or constant factors is, as we have said, the time-object relationship. It is the greatest wisdom of modern painting—a clear awareness by the present century—that in the period when the greatest repertoire of materials and techniques (thanks to modern science and to history) was available, emphasis turned from the decadent viewpoint of technique as a "hidden" means of expression, to technique as a part of expression. That the spectator should be conscious of materials and technique, is the new and revolutionary idea. In Paul Klee, for instance, the process of lithography rather than being a mechanical means for achieving known effects, has restored to it the flexibility of the independent

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

craftsman; it is the lithographic *press,* the physical machine, which he views to be mechanical. The attitude of Klee may, indeed, be viewed as an acceptance of the facts which are basic to the Marriott theory. That is—accepting the limitations upon the artist, as specified by his materials, what latitude there is becomes better realized through an ability to define where the machine's province ends.

One can date this shift of emphasis with Courbet and the Impressionists, or place it later. The point is that in modern painting the finished object, to be most enjoyed, must be looked at with an understanding not only of the technique, but of the flexibility of the technique involved. From the social point of view, this is a resolution of the artist-public distinction. At the period when the artist, because he had no stable economic basis in society, retreated into his *atelier* to paint exclusively to please himself—the public is imperatively beckoned to follow him into the studio, invited in by the painting if not by the man. Never before in the history of painting had the artist spoken so professionally, and with such apt reticence.

From the psychological viewpoint the situation is as healthy, if not as unique. The spectator is deceived when he is ignorant; by the accumulation of knowledge he does not become a *raconteur.*

*II. Characteristics of painting.* The art of painting can be distinguished from the other arts by the diversity of its objects. The range in painting is from tremendous mural decorations made for public buildings, to tiny miniatures fashioned to please the individual owner; from the ultra-sophisticated art of a Redon, a Matisse and a Mondrian, to the commercially calculated illustrations of a McClelland Barclay. The range has been extended with the gradual democratization and industrialization of society, so that a number of crucial issues have arisen regarding the phenomenon of public taste.

The history of painting is more complete than that of any other art in the sense that it covers all ages and civilizations with fewer breaks in the continuity. Even sculpture, which shares with painting the distinction of being a mature art from prehistoric times, has more notable gaps or instances of *lag*—for example, the half dozen centuries which precede the Romanesque period. In these "dark ages" the painting of miniatures for manuscripts, usually of a religious nature, constitutes the one unbroken record of man's imaginative inclination. The portability of the manuscript can alone account for this survival.

PORTABILITY OF PAINTING. But painting is flexible and portable in a still more important sense. One does not, to comprehend a painting, need to know a language in which it is written, or need a translator; an assemblage of instruments and of muscians is not required to bring the art into being. These two factors, differentiating painting from literature and from music, make it in every epoch adapted to exportation—an agent in cultural diffusion whether the maker and owner so intend or not.

UNIVERSALIZING AND OPPOSING TENDENCIES. The portability of painting is inseparable from its tendency to become universal both in its expression and in its formal means. A large chapter in the history of painting is the story of racial and national importations and assimilations. The ancient art of Attica subsides in the incalculable glory of an Ionian Renaissance. Early Christian painting achieves its character from a blend of Eastern and Classical elements which have, faster than the sharp eye of the historian can observe, shuttled back and forth across the Mediterranean. Yet, because of the flexibility of the art, one can see a contrary effort, usually on the part of political and ecclesiastical personages, to make colloquial and specious propaganda out of art.

Prior to the modern era the Byzantine Christian rulers established an iconography, a scheme of objective details, which hampered the fluency of stylistic evolution. The Jesuits, alarmed at the success of the northern Protestant Revolt, perceived that specifications more substantial than the iconographical must enliven the calculated style of a Raphael. Men as dissimilar as Guido Reni and Rubens answered the call, with a febrile sentimentality and a pagan sensuality respectively. The Kings of France, Catholic and nationalist, accepted Rubens, accepted what there was of substance in the Italian Mannerists, and by this masterly judgment effected a four hundred year identification of universal culture with French political fortunes.

In this move the unique element was the nationalism. Louis XIV, by his simple formula of *L'état c'est moi* more concisely even than the Christian Fathers envisioned himself the representative of the Muse in the Western World. It was in large part his regal descendants who modified this splendid vision under the tutelage of the academicians Lebrun, Boucher, and finally David with his

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

equivocal appeal to the ancients—until we are brought up sharply in the 1890's with Gauguin's by-now astonishing revelation that he is not treading and will not tread in the French Tradition—but is sailing off for Tahiti.

THE MODERN PERIOD. No example can better illustrate the connection between cultural diffusion and the art objects's portability than the celebrated peregrinations of Gauguin's curvilinear motif. It has been established that the designs on the clothing of the Polynesians in Gaughin's paintings had been simplified for purposes of cheapness in printing by Manchester (England) cotton manufacturers who were, by the date of the artist's adventures, selling back to the Tahitians these Neo-Polynesian designs. The sequel to this discovery is plain when we reflect how vast, after all, is the British domain—the figures in Gauguin's *Ta matete* being constructed upon an old Egyptian formula, and clothed in cotton presumably from India at a goodly profit: the cut of the gowns being acceptable to Queen Victoria, to the French Missionary Society—to almost all contemporary Western institutions excepting only the official French Salon.

The minds which confront art are, admittedly, as flexible and variable as the art itself. Only so can we explain how the German Library of Information publications, circulated until 1942 in the United States, were able to single out "decadent" painters by a stylistic definition, but had to name the artist when disposing of musicians and writers. Simultaneously the indigenous American publications, such as Peyton Boswell's *Art Digest,* brought to a final intensity their attacks upon these same stylistic tendencies which Hitler hated—but in this instance named individuals, all allegedly members of the "School of Paris". Clearly, most of these names, while not French, were foreign.

In both cases, but by varied tactics, the age-old universalizing tendency in the art was met by the naïve explanation that "emotional instability is racial". And yet, contrarily, it was the portability of painting which finally came in for resentment. Otherwise Hitler, for instance, might with equanimity have permitted the "inferior races" their "inferior art".

*III. The usage of painting.* Aristotle was among the first to insist upon the ethical character of art. He broadly states, for antiquity and for most of the Christian era, the premise which no artist questioned consistently until modern times. In the *genre* of landscape painting where an ethical purpose, blunted by a sort of pantheistic vulgarization of the Deist doctrine, first receives its *coup de grâce,* the traditional purposiveness is only gradually eliminated. Within the "French tradition", for instance, Claude is obliged to insert in his imaginative vistas tiny figures which feebly carry the titles: *Flight into Egypt,* or *Acis and Galatea.* As late as the 1860's, Corot of the Barbizon School (q.v.) commonly lapses, if not into Christian purposiveness, at least into a perfunctorily "humanistic" inclusion of the human figure. But there is this distinction by then: he introduces the human figure and intends in those same years to be a popular painter. He has accepted the limitation which Claude, two centuries earlier, had struggled against.

Parallel to the disappearance of the traditional form of the ethical purpose, comes the modern doctrine of realism—of faithfulness to nature. At first the new approach was suggested as an ethical alternative—and such a rationale still obtains among the uninitiated; but a new tendency has been noted, beginning perhaps with the naturalistic social philosophers, and typified by Zola's alleged "science", to justify the realistic approach as a natural, a sort of organic, way of making a work of art. At its lowest, its least cerebral, level, the argument is easiest to understand and becomes an assertion: "Man is amorphous, let what he makes be likewise." The logical error here seems to be that of the "undistributed middle". The tactical error is to have abandoned the really cerebral level where any man may be a dictator by taste, able to disparage the content of work which does not please him.

FANTASY AND IMAGINATION. The laborious ethics of the nineteenth century and of pioneer art historians so well coincided with what political and religious manipulators had previously demanded of the painter that it has but recently been observed that the art of all periods attains to a reasonable degree of permanence, or is pleasing at least to modern man, when it dodges or exceeds the specifications. The creative imagination of the individual flares up in Giovanni di Paolo, in Sassetta, and therefore provocatively in the very face of the cult of the Blessed Virgin in Sienna. But contemporaneously, in the city of Florence, Piero di Cosimo and della Francesca—yes, and Botticelli—give an equally charming lie to the "realistic purposiveness"

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

which historians have, on the basis of disjointed remarks of Leonardo, fastened upon the whole three centuries of the city's history. We know today that visual representation, rather than being the aim of the Renaissance, was as much the civic predicament as the Medici were in the arriving epoch of the new nationalisms. Realism wore the art out; as Lorenzo the Magnificent, the bitter and smoldering spirit of Vasari's portrait, is too worn out to long accompany Botticelli on his pleasant sojourn with the fragile and poisonous women of Elysium.

The three painters we mention are not the whole of Florentine art. They are merely the titans who enter a distinguished protest, in the appropriate phrases of mythology, at the moment when painting is in a muddle. For the art historian who has staked his belief in evolution on the atmospheric perspective of Masaccio, the linear devices of Uccello and the antomical researches of Castagno or Pollaiuolo, all three painters are embarrassing and "episodic".

Curiously enough Sassetta, the fantastic Sienese generally, Lorenzo Monaco and others whom such an historian as Mather once alleged to be loiterers in the pleasant by-paths of reactionary tradition, come in for some attention (as even in the later works of Mather) with the observation that sometime towards the end of the fourteenth century, what may be identified as a Cosmopolitan Style represented painting in its most fluent, its most imaginative, and most portable form. Mather himself does not observe clearly that a meticulous or learned movement towards visual representation is the colloquial tendency, having largely independent histories in the North of Europe and in the South. It can be said that we view the creative impulse, natural to most who start out wielding the brush, being subjugated by those equally ardent individuals who wield the scepter and the cross. The disintegrating tendency, from Giotto to Ghirlandaio in Italian painting, or from Hubert van Eyck to Van Dyck in Flanders, bears certain marked characteristics; in both regions the patron became specific, a man rather than an institution, and the realism fitted the patron's cause like the glove fits the hand. This, in point of fact—this identification of the artist's vision with the patron's prejudices—is the only kind of realism to which we can accord an historical recognition. Secondly, and curiously, each of these subjugated realists (who are so oddly different in their styles) overshadowed in his time other painters whom subsequent generations accepted as the master realists. In the case of Rembrandt, proposed until recently as *the* realist of all time, the situation is clearest. He had the amazing ability, perhaps because he lived in the seventeenth century, to keep his simple faith and a steady brush while going about the popular nineteenth century task of photographing Jesus. The ethics and the realism, as elements perceived by the public, coincide, ironically but perhaps necessarily, when what we term the "capitalist system" saw it profitable to make this concession. Ary Scheffer and Bougereau can illustrate. They are the accepted painters at the beginning of our really unique modern age in which a popular art (supported by segments of all economic classes) supplants the main creative tradition which must henceforth be carried on by the socially *declasse* painter.

IMAGINATIVE AND FORMAL ORGANIZATION. Most people today agree that the artist creates an object to which he imparts a life which is dependent upon the character of the objective world and the character of his own vision. The varieties of opinion under this definition can be distinguished according to the elasticity with which the person uses the word "vision", and the precision with which he may apply the phrase "objective world". The individualism of the artist is registered partially in his choice of subject matter, in the technique used, in the extent to which he avoids what seems to be mere imitation. But the most baffling of all elements to define is that quality of the imagination which varies for the individual artist and will vary again for his separate paintings. It is the viewpoint, personal and temporal, which existed in the making of that painting, and which, through a process of communication of colors, lines, shapes—yes, and illusions—finds today a new, if perhaps similar existence. Obviously one cannot define any quality which varies so much. Perhaps the best one can do is to hang the painting on the wall.

But the simplest of elements to define in a painting are what we call the formal ones. Since most, if not all, of them are conceived as having only a relative existence—valid as mutually distinguishable—they have a pleasing permanence. One such element is the *linear*, as distinguished from the *pictorial*, quality in painting.

*IV. Systems of classification.* The educator and the research scholar in presenting

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

their material find it necessary to use classifications. The cautious ones will acknowledge at the start that their systems of classification are somewhat arbitrary. But what has been insufficiently admitted is that the oldest systems are particularly arbitrary. The *genre* classification into landscape, portraiture, still life, historical episode, and the like, is arbitrary because it presumes a basic importance of subject matter. The historical classification, as into Italian, French, German and English, is equally misleading, and mainly for this reason: the amount of material which any historian can cover in a given work is sharply limited: and the limitation which he has imposed is, in this case, one which does not imply the excluded material. One can investigate French painting and, unless he is also a good student of Italian art, proceed oblivious to that other great body of creative production. The queer thing is then, that both national and *genre* classifications, which are deduced from the historian who is not concerned with the art object as such, fail in that they are not arbitrary enough.

The most valuable formalist classification to date is that of Heinrich Woelfflin which was advanced in his *Fundamental concepts of art history* in 1915. He outlines five fundamental concepts or "schemes of pure visibility". All these schemes are clearly considered as points of view of the same phenomenon; and in the case of each scheme, the individual work of art is placed somewhere between the plus and minus poles—i.e., regarded as linear or pictorial. One can endlessly place additional paintings within the same scheme, thus adding to an understanding of the concepts rather than impoverishing them. And again, the concepts being arbitrary, an addition to their quantity is invited. The schemes of Woelfflin are contrived with painting in mind, and here show an amazing usefulness. They are scarcely exhaustive of the formal qualities in the individual painting.

Woelfflin first considers the distinction between *linear* and *pictorial*. The former, generically, indicates the conception of objects in their tactile character of outline and plane, whereas *pictorial* indicates the abandonment of drawing as a technique to be seen, in favor of pure visual appearances. The distinction is further amplified and illustrated. Secondly, Woelfflin distinguishes between *vision of surface* and *vision of depth*; thirdly, between *closed form* and *open form*; fourthly, between *multiplicity* and *unity*; and fifthly, between *absolute clearness* and *relative clearness*. The scheme seems to be based originally on perceived differences in the baroque and classical styles. Some day the concepts must be extended, and may perhaps embrace a distinction such as the *geometric* and *amorphous* which will be applicable to both line and shape. Color intensity, hue and tone may likewise be included. Likewise a perception of the tactile character in paint may be opposed to the illusion that materials are not used.

Resistance to the Woelfflin method comes promptly from three sources. The research historian whose main task is to gather information, as dates and iconographical evidence, finds the system too flexible—perhaps too close to the meaning of art—to help him. The college teacher of the newly popular "social nature of art" course finds the Woelfflin system, even if relevant to his own thought, a little beyond the sophomore range . . . but may sense that the fault is not with the sophomore caliber of mind as much as with his grade teachers. Finally, the partisan, academic or modern, may be irritated to see how little the scheme, when applied, offers any compliments either to traditional styles or to the revolutionary and new. Despite what seems to be Woelfflin's personal conservatism of taste, despite his omissions, it may be his failure to make much of the progress-concept that is most obnoxious to the partisan. See Marriott, Charles, "Mind and medium in art", *British Journal of psychology*, vol. XI, 1920; Mather, F. J., *A History of Italian painting*, 1923 and *Western European painting of the Renaissance*, 1939; Woelfflin, Heinrich, *Fundamental concepts of art history*, 1915; Giedion, Sigfried, *Space, time and architecture*, 1941; Mumford, Lewis, "The death of the monument", *Circle*, 1937; Venturi, Lionello, *History of art criticism*, 1936; Wilenski, R. H., *Modern French painters* and *The modern movement in art*, 1927.

**painting, Japanese schools of.** See *Bunjinga; Kanga; Kanō; Maruyama; Nagasaki; Nanga; Otsu; Shijō; Tosa; Ukiyo-e; Yamato-e.*

**painting mediums.** See drying oils.

**painting without bones.** See CHINESE ARTS.

**paint remover.** Most of the paint removers commercially prepared are made up of a number of organic solvents, usually with some addition of wax or paraffin to retard evaporation. Ammonia and other alkaline ingredients are frequently added. —G.L.S.

**pai-tsê.** See SYMBOLISM IN FAR EASTERN ART.

**pa'kua** (Ch.). The eight mystical trigrams employed in divination. See SYMBOLISM IN FAR EASTERN ART.

**Pala art.** See INDIAN ART.

**Palace school of Charlemagne.** See Carolingian art.

**palace style.** See CHINESE ARTS.

**palapore.** Named from palanpur, India. A painted or printed bed cover or wall hanging, usually of cotton. High style in the 18th cent. Today inexpensive East Indian prints are used in large quantities. —G.W.R.

**pale.** See HERALDRY.

**paleography.** See writing.

**palerphone.** See phonograph.

**Palestinian folk songs.** See JEWISH MUSIC.

**palette.** A figurative as well as a literal meaning has been given to this term. According to the former it is used to designate the system of color employed by a painter in a given work. Literally, it is a surface of any kind on which the paint is mixed in the actual process of picture making. In Europe since the early Renaissance the typical palette has been a thin piece of hardwood with a handle or with a thumb-hole providing an easy grip. The paint, ordinarily in an oil medium, is disposed in small lumps around the edge and mixtures are made towards the center. —G.L.S.

**palette knife.** According to modern usage, this is a spatula with a thin, rounded, flexible blade. With it the paste-like oil paint is mixed and placed on the palette. The palette knives of the Renaissance, as shown in paintings of that period, were usually of a heavy blade and pointed. Probably they were not designed specifically for this purpose. —G.L.S.

**Palissey enamel.** See CERAMICS II.

**pall.** See HERALDRY.

**Palladian style.** An architectural style attributed to the Italian Renaissance architect Andrea Palladio. The principle feature, monumental in character, consisted of an arch supported on each side by a free standing column, sometimes twin columns, and a pilaster. A fine example of the style is the added arcades in 1549. —O.M.S.

**pallet.** *Book.* (1) A tool used for spreading gold-leaf. (2) A tool, usually a line or ornament for lettering and decorating the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

backs of books. (3) The type-holder for loose letters, etc., for tooling the covers. —H.E.S.

**palliotto.** See altar.

**palmette.** Also called anthemion; a classical conventionalized ornament resembling a palm leaf, a vertical unit with radiating lobes arranged symmetrically and of decreasing height on either side of a central lobe which rises to the highest point. —L.T.S.

**pandora, pandura.** See MUSICAL INSTRUMENTS.

**panel.** (1) Painting supports of wood are usually designated as panels. The great bulk of European easel painting from early Christian times until well into the 17th cent. was done on such supports. Large panels were made of many pieces of wood joined together with dowels and frequently with cross battens to give them additional strength. The kinds of wood varied from one region to another, oak and pine being rather more common in the North, poplar, lime, willow, and nutwood in Italy. (2) A compartment, sunk or raised, in walls, ceilings, doors, wainscoting, etc. —G.L.S.

**panel-in-a-frame construction.** See FURNITURE.

**Pan-Ku.** In Chinese myth., the first conscious being, who shaped the world out of chaos.

**panorama.** See STAGESETTING.

**panoramic sketch.** See military sketching.

**Panpipes.** See MUSICAL INSTRUMENTS.

**pantheon.** From the Greek *pan* all, *theios* divine—hence a temple consecrated to all the gods. Under this definition, among many ancient temples, the most famous is the Pantheon in Rome built by Hadrian (120-124 A.D.) on the site of an older temple erected by Agrippa in the year 25 B.C. This building was partially destroyed by fire in the reign of Titus, restored by Domitian and struck by lightning and again burned in the reign of Titus. The portico of granite columns and superstructures are all that survive of Agrippa's building. The great rotunda, 142 feet in diameter, with its coffered dome was the work of Hadrian, and constitutes the most perfectly preserved relic of Roman antiquity now extant.

The dome is built in a most complex system of mutually sustaining brick arches dividing the immense surface into relatively small units which could receive successively the concrete fill and obviate the use of extensive wood centering. In the modern application of the word, *Pantheon* signifies a building consecrated to famous men. This significance was first applied to Soufflot's Pantheon in Paris. The dedication reads: "Aux grands hommes la Patrie Reconnaissante." Built between 1764 and 1790, it incorporates innovations in design and construction of daring and unprecedented character. Metal reinforcements concealed within the stonework permit a tenuity of proportion of incredible lightness. In a manner, these metal devices anticipate the concealed metallic framework or reinforcements now used. See *Agrippa's Building Activities in Rome,* F. W. Shipley, Washington Univ. Studies, Aug. 1933; *Architecture of Greece and Rome,* Anderson & Spiers, 1925. —L.H.

**pantograph.** Made for changing the scale of a drawing or for copying with such a change of scale, this is an instrument which operates by a system of levers. One point is fixed, one arm is set with a pencil so adjusted as to be in contact with a piece of blank paper, and another arm connected with it has a pointer that is moved over the work to be copied. —G.L.S.

**pantomime.** A drama presented purely by mimics and bodily movement (gesticulation), without the aid of speech or song, but generally accompanied by instrumental music.

**papal tiara.** See tiara, papal.

**paper.** Known commonly as a support for drawings and prints, paper has served also to carry paintings from the earliest recorded history of the art in the Far East and from the time of the introduction of paper into the West. By the 2nd cent. A.D. the Chinese were manufacturing paper and by the 12th cent. the method coming through the Near East had become well established in Europe. It was made in Morocco in 1100 and paper factories were set up in Italy and in France by the end of that century. The Oriental paper seems to have been made directly from plant fibre. In Europe it was found that cotton and linen rags could be broken down into separate fibres and this used for paper making. Such a material still serves as the source of the best papers available. All of them were made by hand until at the very end of the 18th cent. the paper

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

machine was developed in France by Louis Robert. Somewhat earlier than that, preliminary work had been done in the manufacture of paper from wood or plant fibres and, as these methods developed, much cheaper paper became possible and displaced the rag product for less important work. Wood-pulp paper is weaker and more apt to discolor than that made from rags, but it varies a great deal in its strength and stability according to the method of manufacture. Mechanical wood-pulp is hardly more than sawdust which has been matted into sheets. There are various methods of preparing a chemical pulp, all of which produce fibres of greater strength than those made by mechanical means. —G.L.S.

**paper heraldry.** See HERALDRY.

**paper mark.** The handmade papers are settled or felted over a screen called a deckle. The wires of this leave fine marks in the paper, particularly visible by transmitted light because along those lines the amount of fibre is actually less. In the 13th cent. designs were put into the wires of the deckle in order to indicate the manufacturer and these came to be known as water marks or paper marks. They are found in products of the mills of Bologna and Fabriano between 1285 and 1295. By the 16th cent. not only the name or device of the maker but also the date of manufacture was frequently shown. —G. L. S.

**paper painting.** See CHINESE ARTS.

**papier collé.** See collage.

**papyrus.** The forerunner of paper in the West, papyrus was an ancient writing material developed in Egypt and made largely in the Nile delta, at least from the time of the Old Kingdom. By the 10th cent. A.D. paper had displaced it. It was formed directly from the reed, *Cyperus papyrus* of Linnaeus. Strips of the cut reed were laid across each other at right angles, soaked, pounded flat, and dried in the sun. —G.L.S.

**paraffin.** See wax.

**paragone** (comparison). The question of the comparative rank of the different arts as expounded in the theoretical literature of the Italian Renaissance. First elaborated by Leonardo da Vinci the paragone became a favorite theme of literary discussion from the 16th to the 18th cent. The answers to the problem, although varying according to individual predilection, reflect the striving of artists as a class to win recognition for their profession and to raise its standing above that of a mechanical art (q.v.). —R.B.

**parallel perspective.** See PERSPECTIVE.

**parapet** (L. *parpare,* to guard; *pectus,* breast). A low protecting wall about or near the edge of a roof, platform, or other raised or elevated area. —J.M.M.

**paraphrase.** *Mus.* An arrangement or transcription of a composition; generally of a showy and florid character.

**parchment.** Any moderately good skin prepared without tanning and used for writing or painting has been called either parchment or vellum. As a rule, the latter term has been given to finer skins, those of newborn or still-born calves, goats, or lambs, and most parchment comes from one of these animals. It is prepared by washing, treatment with lime, removal of hair, successive scraping, paring, rubbing, and dusting. Characteristically, parchment is pale and smooth. The word itself comes from Pergamum, and the tradition is that Eumenes II (197-198 B.C.) was largely responsible for the development of its manufacture. It remained the best support for writing until comparatively modern times, although for general purposes paper had begun to displace it by the 13th cent. —G.L.S.

**parge work.** A method of molding ornaments into plaster walls and ceilings. Popular during Tudor (q.v.) period. See INTERIOR ARCHITECTURE AND DECORATION.

**Parian marble.** Quarries on the island of Paros produced the finest marble known to the Greeks for sculpture, and from it their best statues were usually made. It has coarse crystals, which absorb and reflect the light, giving an extraordinary lively, luminous glow to the surface. Hence it is unexcelled for the representation of vitality and sensuous charm. —W.R.A.

**Parian ware.** See CERAMICS II.

**Paris blue.** See Prussian blue.

**Paris green.** See emerald green.

**parish planning.** See CIVIC PLANNING.

**park system.** See CIVIC PLANNING.

**parkway.** See CIVIC PLANNING.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**parlando.** *Mus.* "Speaking"; in a declamatory or recitativic style. See OPERA.

**parquetage a plat.** See RESTORATION OF PAINTINGS.

**parquetage de champ.** See RESTORATION OF PAINTINGS.

**part.** *Mus.* Section of a composition; voice (in choral music); melodic line (in polyphony, also called voice); music sheet used by a performer in an ensemble; character in a play. —E.K.

**parted coats.** See HERALDRY.

**partial.** See ACOUSTICS; harmonic analysis.

**participation.** It has been generally recognized that the work of art is both an imitation and an expression—*similitudo expressiva,* to quote St. Bonaventura—of its theme. That the material work also *participates* in the reality of its thesis is often overlooked. "Participation" means that the formal cause (or meaning) is really *present* in the actual shape of the work of art. For example, in a statue, the form of a man is presented in a nature of stone; by that idea the statue is informed, or if not it would be a shapeless, informal mass of material. This can be completely misunderstood if it is taken to mean that the formal cause is *physically* present in the effect, adequacy then amounting to identity. On this basis Levy-Brühl (whose point of view is now generally discredited) revived the term "participation" (which he called "mystic") in connection with a supposed "primitive mentality" in which the symbol is confused with its referent (as in fetishism).

The perennial philosophy, however, has always assumed that all existences are what they are "by participation" in their principle: "et Plato posuit homo materialis est homo per participationem" (St. Thomas Aquinas, *Sum. Theol.* I.18.4); living things "participate" (*vbhaj*) in "not-dying" ,RV. I.164.21); and as Aristotle points out (*Phys.* IV.2.3) Plato in *Timaeus,* 51 A equates matter in extenso with "that which can participate" (metalambáno) in form. This necessarily involves the case of art, which is always an embodiment of form in matter; the form or idea being immaterial. In works of art, then, things participate (metécho) in the forms after which they are named, and to say that they "imitate" these is the same as to say that they "participate in" them (Aristotle, *Met.* I.6.4, cf. Plato, *Parmenides* 132 E—133 A, and *Phaedo* 78 E). Accordingly, the work of at the same time, imitates, expresses, and participates in its form. See Przyluski, J., *La participation,* Paris, 1940; Coomaraswamy, "Imitation, Expression, and Participation" in *Journ. of Aesthetics and Art Criticism,* vol. 3, 2, 1944. —A.K.C.

**partimen.** See MEDIEVAL MUSIC.

**partita, partie.** *Mus.* A suite. A set of variations.

**partition lines.** See HERALDRY.

**partridge breast.** A term applied to a special glaze of light streaks seen on *Temmoku* ware.

**part-song.** A song for two or more independent voices or parts.

**party per pale.** See HERALDRY.

**parvenu.** See POST-REVOLUTIONARY ARCHITECTURE AND DECORATIVE ARTS IN THE U. S. A.

**pas** (Fr. step). While literally singular, *pas* usually refers to combination of steps, steps meaning not only movements of the feet but attendant conformations of arms, trunk and head. In the academic vocabulary a *pas* also denotes a dance number, a solo, *pas seul,* a duet, *pas de deux,* etc. From this, a *pas de guirlandes* refers to a number using garlands, a *pas de chale,* a shawl, etc. Individual steps have mimetic or associative conditionals, *pas de chat,* cat step, *pas de basque,* etc. —L.K.

**pas de basque.** A movement in the classic academic vocabulary, ostensibly deriving from a basque folk dance of the 18th cent.

**pas de bourée** (Fr. *bourée* (q.v.), 18th cent. quick dance from Auvergne). Like many other terms originally used to describe social or folk dance, the *bourée* is a specific appellation for a type of stage movement in which the female dancer propels herself across the stage, on points, in an imperceptible shift of the toes, the knees scarcely bent. —L.K.

**pashim.** Soft downy wool growing next to the body of a goat. In color it is white, dark gray, or drab and of this many of the finest India rugs are woven.

**paspy.** See passepied.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**passacaglia, passecaille.** One of the *pre-classic* dance forms, was probably a Spanish folk dance of ancient origin, which found its way into 16th cent. European court festivities. The little information we have indicates that it was danced as a solo, with great solemnity, in slow 3/4 meter, and resembled the chaconne. Early musical suites sometimes contained pieces bearing the name *passacaglia,* and arranged in *air on a ground bass* form. If the original dance was a solo, it seems scarcely possible that it could have been the source of the above musical form. At least two dancers would have been required—one to perform the *bass* and one the *air,* since, in music at least, the two must at some time occur simultaneously (see chaconne). —J.G.

**passage.** *Mus.* (1) A short transitional section of a piece. (2) A rapid figure, as a scale passage called a "run".

**passage, passageway.** A way, channel, corridor, or hall affording a means of passing or communicating.

**passant.** See HERALDRY.

**passepied.** A member of the *pre-classic* group of dances, the *passepied* was borrowed from the Breton peasants by the court of Louis XV. In its ancient folk form, the dance was known as the *branle of Brittany* and was performed as a pantomime in 2/4 or 3/8 meter. The basic movements were a peculiar pawing action with the feet and a light, gliding step in which one foot was crossed over the other. The swinging rhythm of the dance in its 3/8 form suggests that it may have been an ancester of the waltz. Following the usual adoption procedure, the passepied underwent over-refinement and formalization through courtly performance in simulated pastoral settings, but its characteristic steps became a legacy to the ballet, and its music appears in some of the classic instrumental suites. —J.G.

**Passion.** In the Roman Catholic services during Holy week the story of Christ's sufferings and death are told in the four Gospels. Originally it was chanted by three priests; during the 16th century harmonized passages were introduced. In Lutheran services the Passions have become complete oratorios due to the addition of chorales and reflective passages. Bach's St. Matthew Passion is considered one of the finest.

**paste.** Any of a group of adhesives made chiefly from flour or starch is called paste. The simplest preparation is by cooking the flour in a suitable quantity of water. The flour itself consists of a mixture of gluten and starch. A somewhat smoother paste is made from the starch alone, that from rice, wheat, corn, potatoes, and arrowroot being capable of furnishing a good adhesive. The best preparations usually contain some amount of other ingredient such as animal glue and, to be kept for any length of time, need to have a fungicide added. Their particular value is for joining together pieces of paper or similar light materials. —G.L.S.

**paste mold.** See GLASS AND GLASS-MAKING.

**pasteboard.** *Book.* A (card) board made by pasting sheets of paper together. Also made with pulp and moulded.

**pastel.** A picture made with a paste of pigment mixed with gum water; frequently regarded as painting.

**pastophory.** See EARLY CHRISTIAN ART.

**pastoral, pastourelle, pastorale.** Music in rustic style, generally in 6/8 or 12/8 time. See MEDIEVAL MUSIC.

**patchwork rugs.** Made by applying bits of colored cloth to a foundation—usually black or very dark heavy cloth. The applied pieces were cut to resemble flowers, foliage and other motifs and were in varied colors. The ornamentation of bunches of flowers, wreaths, baskets or vases of flowers, trailing vines showed to advantage on the dark backgrounds. —B.E.J.

**patera.** A circular ornament, resembling a shallow dish, often used in decorative work, esp. bas-relief.

**pater noster.** A beadlike ornament in moldings.

**pâte sur pâte.** A process with successive layers of white and colored slip applied to a dark ground—an impasto decoration. See CERAMICS II.

**patine, patina.** Any coating on the surface of an object that has been accumulated by aging; more specifically, the corrosion of old bronzes and other metallic objects caused by chemical reactions with ingredients of the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

atmosphere, earth or water with which they have been in contact. Recent works are sometimes subjected to chemical treatments which duplicate the various types of patina formed on old pieces. Although the commonest type of bronze patine is bluish green or blue, nearly every hue is to be found on ancient metallic objects depending on the composition of the object and the conditions to which it was exposed. See *Encyclopedia Britannica,* 14th ed.; *The Artists' Handbook of Materials and Techniques,* Ralph Mayer, 1940. —R.M.

**pattern.** See design.

**paua shell.** Similar to mother-of-pearl.

**paulownia.** See SYMBOLISM IN FAR EASTERN ART.

**pausa.** See NOTATION.

**pavane.** One of the group of ancient dance forms now called *pre-classic.* Originally a Spanish folk dance, it early became incorporated into church ritual and was danced at the Spanish court of the Inquisition. The name was derived from the Latin *pavo* (peacock) and suggests the arrogant dignity and pomposity of the dance. The pavane became the opening dance of 16th cent. European court balls, where it assumed the manner and proportions of a processional pageant. When French composers began to write instrumental suites for court festivities, the pavane music took its place as the opening piece, and continued as such long after the suite lost its association with actual dances. The meter of the pavane was usually 2/4 or 4/4, played very slowly by wind instruments with a repeated drum figure accompaniment. In movement, the dance was fairly simple, using variations of a slow, gliding walk. It was danced by couples circling the room. Solos by the men sometimes were inserted between the advancing and retreating figures. —J.G.

**paysage** (Fr.). A landscape picture.

**peach loom.** A type of Chinese pottery, the glaze of which resembles the bloom of a peach.

**peach of immortality.** See SYMBOLISM IN FAR EASTERN ART.

**peacock.** See pavane.

**peasant art.** See folk art.

**pedal harp.** See MUSICAL INSTRUMENTS.

**pedestal.** The base for a column, statue, etc.; usually circular, square, or rectangular, rarely polygonal.

**pedigree.** See FORGERIES IN PAINTING.

**pediment.** The triangular space at the end of a sloping-roofed building, or a decorative feature of that shape. The filling of this space was one of the most important problems confronting Greek architectural sculptors, since the gables at the front and back of the temples were the most conspicuous field for decoration. Their progress in making their designs contribute to both the religious and artistic effect of the building was rapid, in spite of the difficulty of adjusting a number of figures in harmonious relationship within such a difficult space. The center must be the focus of interest, with the chief accent; the angles must be adequately filled; and within the intervening space figures correct in scale must be built up in a steady, unbroken rhythm. In early temples, animals or serpents were used to help fill the space, but by the beginning of the 5th cent. B.C. at the temple of Aphaia at Aegina the sculptors succeeded in building up a pattern of reclining, kneeling, advancing, falling and standing figures in a series of interesting geometric forms; they were not, however, related by a continuous rhythm. The Olympia pediments (460 B.C.) show advance in both the monumental character of the forms and drapery and a steady rhythmic beat from corner to center; and in the Parthenon the fusion of geometric form, naturalistic modelling, and monumental power was unexcelled. There the figures were set at various angles, so that they emerged from the background in three dimensions; the weaving of drapery, lateral as well as around the figures, established a continuous rhythm; and the massive forms gave additional strength to the noble architecture. Not only in artistic design, but also in pictorial representation, they contributed to the significance of the building, picturing on the east end the birth of Athena and on the west the struggle between Athena and Poseidon for the lordship of Athens. No later pediments approached them in beauty; most, in fact, have been left empty of sculpture except for mouldings around the edges. In Hellenistic times the central space was sometimes filled with an

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

imposing group, but corners were left vacant. The Roman pediments, higher than the Greek, occasionally had a central group on a podium, but failed to fill the rest of the space successfully. The pedimental shape was used by the Romans as a decorative element to crown doors and windows, a device inherited and widely used during the Renaissance. Baroque buildings elaborated on this type of decoration. Pedimental sculpture was revived, more or less successfully, in modern Europe, and has been used on many American state capitol buildings. Interesting contemporary adaptations of Greek sculptured pediments are those on the Philadelphia Museum and the Supreme Court building in Washington.
—W.R.A.

**Peisistradid era.** See HELLENIC ART.

**pen.** Probably the common pen used traditionally for writing and drawing in Europe was that made from a quill cut, split, and pointed as the writer or draftsman wished it. The reed pen was not uncommon, however, and probably had been known from earlier times. It was usually made from the tubular stock of fine, hollow bamboo or of coarse grass, and was cut in much the same way as the quill. Metal pens have been known in ancient times but machine manufacture during the 19th cent. allowed them completely to displace the older implements.
—G.L.S.

**pencil.** A brush of hair or bristles used to lay on colors. Manner or skill of an artist, his own artistic style.

**pendants, vaulting.** Elongated voussoirs supported by transverse arches from which the vault ribs spring. The lower ends of the voussoirs project below the vault, forming pendants which are often elaborately carved. This type of vaulting was developed during the late English Perpendicular period of Gothic architecture. —O.M.S.

**pendentive.** The transitional vaulting, usually triangular in shape springing from the corners of a structure with a square or polygonal in plan. Byzantine vaulting is a typical example. —O.M.S.

**penetrative seeing.** See PHOTOGRAPHY.

**Penglai-shan** (Ch.). Buddhist land of eternal spring—paradise.

**pen process acquatint** (an intaglio process). The pen process aquatint, though it had been used most effectively by Gainsborough (1727-1788), seems to have been lost until recent times when it was rediscovered by modern artists in search of unique new mediums.

In the finished proof, the pen process is similar to a pen or brush drawing. The clean copper plate is drawn on with brush or pen using a special ink that has a high sugar content. The plate is heated and a regular hard etching ground is rolled on the plate over the ink drawing. The plate is now immersed in cold water and with the help of a piece of cotton batting the ink dissolves, leaving bare copper wherever the pen or brush drawing had been. If bitten in this state, the more open places would produce *crevé*. To overcome this, the plate is now put into the aquatint box and an aquatint ground is laid on the entire surface. This converts what had been brush or pen lines into areas of aquatint which are now bitten and printed in the same manner as any etching. Usually the pen process is followed up by subsequent tones of pure aquatint.

The pen process is quick, comparatively easy and certain. It is capable of almost as many variations and nuances as brush and pen, but with the added charm and preciousness of a print. —K.K.

**pentachord.** (1) An instrument with five strings. (2) A diatonic scale of five notes.

**pentacle.** A certain figure formerly used as a magic symbol, as a five-pointed, or a six-pointed, star.

**pentaptych.** Often used in connection with a series of five prints which have been composed as a series.

**pentatonic scale.** The five note scale represented in its simplest forms by the symbols C-D-F-G-a, or D-F-G-a-c, or F-G-a-c-d, etc. If the series is continued, the 6th tone is in every case an octave higher than the first. The underlying structure of primitive music, Scotch music and many of the eastern exotic musics is pentatonic. See scales and modes. —V.A.

**Pentelic marble.** Quarries opened late in the 6th cent. B.C. in Mt. Pentelicon, north of Athens, provided marble for the buildings of Athens and for much of the sculpture in Greece and Italy, although often heads of statues were made separately in the finer Parian marble. Pentelic marble is white, with fairly small crystals and sparkling quality.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

It contains iron, the oxidation of which is responsible for the present rusty gold tints of the Parthenon. —W.R.A.

**pentimenti.** Used to describe paint ridges existing under the finished surface of an oil painting. These ridges usually indicate earlier states of the picture. —H.M.

**people and things painting.** Chinese name for genre painting. See CHINESE ARTS.

**peplum.** (Latinized form of the Greek word *peplos*). A large, full robe worn by women, generally of heavy material in contrast to the lighter and more elegant chiton (q.v.). It was a rectangular piece of wool or linen the upper part of which was doubled up. It was fastened on the shoulders by fibulae or clasps and was worn with or without a belt. For illustration, see Margarete Bieber, *Griechische Kleidung,* Berlin, 1928. —L.L.

**percussion instruments.** Drums, gongs, triangle; the pianoforte may be regarded as the highest type of percussion instrument (percussion = striking together). See MUSICAL INSTRUMENTS.

**percussion sticks.** See MUSICAL INSTRUMENTS.

**percussive movement.** See quality.

**perfect interval.** See interval.

**perforated.** See SCULPTURE.

**performance** (musical), **theory of.** See MUSICAL PERFORMANCE, MAIN TRENDS IN.

**performance score.** A scientific music or speech score showing graphically exactly how each sound was rendered in a performance. The record is made by phonophotography (q.v.). The term was coined in the Iowa Psychological Laboratory and is abundantly illustrated in the publication emanating from that and similar laboratories.

"The photographic record on special moving picture films, as described for a five-minute song, may contain thousands of specific facts bearing on the tonal, dynamic, temporal, and qualitative aspects of every note of the song, each measurable and exactly definable. We were at first baffled by the accumulation of such masses of data without any simple way of sorting and representing them. A solution was found in the design of what we now call the performance score. In its simplest form it is somewhat like the ordinary musical score.

"In such a score we can see as much detail as may be significant. It is customary to record frequency, amplitude, duration, and form of sound waves—the correlates of pitch, intensity, —and time in this manner; and then, because of the great complexity of the timbre, to represent fair samplings of tone spectra separately. Having once adopted this idea of representing four elements of the song graphically, that scheme may be applied to any particular feature of music or speech sound studied in detail; for example, phrasing scores, rhythmic patterns, the vibrato, or the harmonic structure of the tone. All elements of the sound are represented graphically to the eye.

"This recognition is analogous to the fact that a picture of an object can be represented adequately in three dimensions of space and in color. The painter has the means of representing in a single picture all desired degrees of variation in these three dimensions of space and a vast variety of variants in color. Imagine for a moment how helpless we would be if it had not occurred to someone that all types of objects and situations could be represented in pictures. That would be analogous to the situation in which we found ourselves in music. The performance score is a unified picture in three of four dimensions of music as it is actually performed. Of course the reason we have not had such pictures until recently lies in the fact that the means of making them were discovered only recently through the invention of sound photography.

"Just as the recognition that every feature of a musical rendition can be represented in terms of four elements brought order out of chaos in the laboratory measurement, so now the adoption of various types of performance scores representing each of these four elements complements this by enabling us to assemble and interpret great masses of facts in terms of a fairly simple picture. Without such language and pictorial interpretation, most of the findings of the camera would have been lost. One can get some conception of the mass of material contained in a performance score if he realizes that for each note in the original musical score, there is a graph showing exactly the form of attack and release and all the minute changes in pitch and loudness during the body of a tone with the time and rhythmic value of each element of change during the tone.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Every element in the actual phrasing is shown; yet the score is so compact that it may not occupy more than twice the space occupied by the original musical score.

"To the musician, it seems almost incomprehensible that much of which we are aware, for example, media for the expression of musical feeling, can be represented in simple, accurate, and definable language and pictures. Before we realized the full significance of this, we in the laboratory were quite as helpless as is the musician in attempting to represent effectively what seems to be a chaotic mass of detail.

"It may seem like straining a point to say that the device for throwing all the hundreds of findings in a musical selection into a comparatively simple picture which we call the performance score is analogous to the adoption of terminology in the biological and physical sciences or in mathematics. But it may seem stranger still to assert that the performance score representing the world of music is to what we can hear as the painting or photographing of objects in color and relief is to what we can see in nature or art." Seashore, *Pioneering in Psychology,* University of Iowa Press, 1942. See Seashore, *Psychology of Music,* 1938; Iowa Studies in Psychology of Music, vols. 1, III and IV.

—C.E.S.

**periaktoi.** See STAGESETTING.

**Periclean period.** During the years 461-429 B.C., when Pericles was the leader of the Athenian democracy, Athens produced art of the highest quality in many fields. Social conditions were favorable for such expression; men worked "in the fearless confidence of freedom". The city was a democracy, with direct control of its affairs, local and international, in the hands of all the male citizens. Most officials were chosen by lot for one-year terms, so that there was a wide distribution of political office, and pay for public service insured that even the poorest citizen could afford to serve. Although political rights were denied to women, resident aliens, and slaves, all but the women had a large amount of economic and social opportunity; and regardless of their status men were encouraged to contribute what they could to the community. Many of the aliens were skilled craftsmen, encouraged to come to Athens to exercise their ability; and slaves (captives in war) were often able artists whose skill was recognized and given an opportunity to function happily. As Pericles said, "We honor ability in every branch of achievement, not on class or sectional grounds, but on the basis of merit alone." It was therefore no leisure-class culture which produced the drama, religious, musical and athletic festivals, and plastic arts, which flourished then as in few other periods of human history; rather it was a community of men working together on a basis of greater genuine equality than has often been achieved in any time or place that created and controlled the life of the city. During this period Athens also governed an empire of some 250 states, and might properly be called the capital city of the eastern Mediterranean. The tribute money from these states was partly responsible for Pericles' great program of art projects.

In stating his ideals for Athens Pericles declared: "We have provided education and recreation for the spirit, festivals throughout the year, and beauty in our public buildings, which delight our hearts day by day as we see them and banish sadness. We love beauty without extravagance." It cannot be emphasized too strongly that art in this society was regarded as a normal and necessary expression of the common life, and was created by and for the people. Artists were commissioned by the city rather than a wealthy few, and the vitality of their art may fairly be attributed to the fact that they were employed on the basis of merit, served community purposes and needs, and were constantly criticized and appreciated by a population interested in and sensitive to their work.

The most important art project was Pericles' great building program, instituted to relieve unemployment, keep the residents happily engaged in productive work, and make Athens a cultural capital. Six major temples, the entrance hall to the Acropolis, the Hall of the Mysteries at Eleusis, and a music hall were the chief buildings erected. Pericles also brought the famous city planner, Hippodamus, from Miletus to lay out the port city of Piraeus on geometric principles. Buildings were planned cooperatively by state officials, architects, sculptors, and, it must be added, an interested and critical public. The most impressive temple was the Parthenon, dedicated to the patron goddess, Athena, with its noble logic of plan, enlivened by delicate variations and refinements and enriched by sculpture of surpassing beauty. It serves as a symbol of the fusion of power

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

and grace which characterized this period of Athenian life.

In its sculpture Periclean Athens likewise achieved a synthesis of Doric power and Ionic grace. Myron and Phidias were the outstanding names, but a host of other sculptors also made their contribution to the city's prestige, picturing the gods, the heroes of the Greek past, and statesmen and athletic heroes of the present. This sculpture was essentially idealistic, with strong planes vigorously modeled, sensitive handling of line, and a sturdy sense of logical design. During the same period Athenian mural and vase painters were actively engaged, and demonstrated a similar breadth of design and well-disciplined power. Their subjects were also of community interest: the exploits of gods and heroes, and scenes from the gymnasium, festivals, and home life. The same educated public taste appears in the minor arts of the time, including dress, furniture, and jewelry.

Athens demonstrated how successfully art, regarded as a public service, can flourish under democratic auspices, and how great a contribution it can make to community happiness. —W.R.A.

**pericope.** The Greek word for evangelistary. It was called pericope from *perikopein,* which means to cut, so called because the Gospels were cut into sections for use on the consecutive Sundays of the church year. A famous pericope was among others, the pericope of Henry II. School of Reichenau, between 1002 and 1014, now in the Munich State Library. See miniature; initial.—A.J.S.

**periodic.** *Cer.* Intermittent. Kiln fired not continuously. See CERAMICS I.

**period of the Early Republic.** See POST-REVOLUTIONARY ARCHITECTURE AND DECORATIVE ARTS IN THE U. S. A.

**peripteral.** With a line of columns on all sides.

**peristasis.** See HELLENISTIC ART.

**peristyle** (Gr. *peristylon* fr. *peri,* around + *stylos,* column). In Greek and Roman architecture, a covered colonade surrounding (1) the cella of a temple, or (2) an open interior court, as in a house or a gymnasium; also the whole court so surrounded by a colonnade, especially of a house. —L.T.S.

**permanent collection.** See exhibition.

**PERSIAN ART.** In 559 B.C. Cyrus the Great assumed the leadership of the Persians, who were a subordinate Iranian tribe, and in 550 he conquered the Medes, a superior branch of Iranians, thereby laying the foundation of the Persian Empire. Throughout all Persian history the geographical boundaries have been constantly shifting, and all the peoples concerned, either near or far, have at some time exerted an influence on Persian art. The capacity of the Persians to absorb and utilize these impulses is one of the outstanding characteristics of their genius and is noted at the very outset, in the **Achaemenid Period,** 559-331 B.C. In the palaces of Darius and Xerxes at Persepolis the hypostyle hall which had already been employed by the Medes is found mounted on a limestone platform recalling Babylonian and Assyrian terraces, though it may have been a simple answer to the problem of defense. Typical of the Persians are the square rooms demanded by their obsession with symmetry and the tall, slender, widely-spaced columns with their multiple flutings and ornate bases and capitals, which convey an effect of elegance that is remarkable in all Persian art. The stone facings of the platform, stair-railings, etc., were carved with reliefs representing the king sacrificing or hunting, guards and soldiers, subject peoples bearing tribute, animal combats, etc., all tending to glorify the deity through his earthly representative, the king. On one half of the buildings are 1,000 feet of reliefs, which are repeated on the other half reversed as in a mirror. Although everything connected with the structure is subordinated to the master architectural plan, just as it was in Babylonia and Assyria, this does not mean that the sculpture, for example, is weak in itself, but only that it loses by being removed from its context. As a matter of fact, the sculpture is simple and powerful, its meaning gaining emphasis from the total absence of insignificant details; and this poignancy is not limited to work in stone, but is seen also in brick-tile reliefs and esp. in metalwork, in which ibexes, bulls, and lions of bronze, and the animals adorning gold and silver are all graced with a carefree, sprightly robustness reminiscent of archaic art. Such metal objects were either cast or beaten and were decorated by embossing, engraving, inlaying, or the setting of paste or stones in gold cloisons.

The Achaemenid Empire was conquered by Alexander the Great in 331 B.C., and for the next 5½ cents. the territory was ruled by the Seleucids or the Parthians (Arsacids),

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Artistically, as far as Persia is concerned, the period is not very important.

In A.D. 226 Ardashīr, who claimed Achaemenid ancestry, usurped the Parthian throne and established the second national Persian dynasty, the Sāsānian. The unification of the country early in the period encouraged the pursuit of constructive activities, and the resultant production of architecure and works of art has been the envy and the pattern of succeeding generations. Mazdaism, the religion of Zoroaster, became for the first time the state religion, and most of the buildings and other works were designed as in Achaemenid times to impress upon the people the omnipotence of the deity and his servant, the king. Unlike the Achaemenid palaces, which were light and open, the Sāsānian structures, such as e.g. Fīrūzābād, Sarvistān, Tāq-i-Būstān, were massive, overpowering monuments with vaults and domes, built sometimes of rubble and mortar, sometimes of stone, with domes of brick and frequently decoration in stucco. The influence of the Sāsānians on later architecture can be surmised from the fact that they developed the vault and the dome and invented the squinch and the axial plan. Only one statue in the round is known: a three times life-size figure of Shāpūr I at Bishāpūr, the style of which is derived from 2nd cent. Indian statues, such as the one of Kaniska at Mathurā. Most of the extant stucco decoration is given to geometric and floral patterns and animals, but the main sculpture is relieved in the stone of the façades and is devoted to divine investitures of kings, royal triumphs, hunting scenes, etc. Although each scene is based on a particular event, either real or symbolic, the portrayal is ideal, which accounts for the supremacy of spiritual content over anatomical accuracy. The simplicity and directness of the statement, the dignity of the participants, and the skill of the modelling combine to give an effect of intellectual power that is rarely found anywhere. Typically Persian is the aristocratic grace with which even the most robust figure is imbued. These same qualities are found in the repoussé animals and hunting scenes of the silver dishes and in the heraldic beasts and birds of the silver ewers and silk textiles, which last, like contemporary Byzantine silks, show unusual strength of design for such basically delicate objects.

The constant fighting of the Sāsānians finally weakened them to such an extent that they fell an easy prey to the Arabs in A.D. 641, but the uncivilized Arabs knew little of statecraft, and thus the Caliphate, which they immediately set up, was forced to employ Persians in high administrative positions. The removal of the Caliphate from Damascus to Baghdād promoted its gradual Persianization at the same time that the Persians, though not required to adopt Islam, were becoming progressively Islamicized. Perhaps the strongest bond was forged in the northeast by the semi-independent Persian Sāmānid dynasty of Khurāsān, which substituted the Arabic script for the Pahlavī of the Sāsānians and established the modern Persian language. In 990 the Sāmānids succombed to the Ghaznavid Turks, who, in 1037, were overthrown by the Seljūq Turks. The Seljūqs took all of Persia, establishing their capital at Rayy (Rhages) and reinstating the Caliph in Baghdād, he and his immediate predecessors having been puppets of the Buwayhids.

Another Turkish dynasty, the Kwārazmshāhs, acquired certain territories from the Seljūqs, and it was the last of their rulers who slighted Chingiz Khān, thus bringing on the Mongol conquest (1220) and destruction if large parts of Persia. The rule of the Mongol Il-Khāns lasted until 1336, after which the country was divided amongst local dynasties until, in 1369, Tīmūr (Tamerlane) inaugurated the Tīmūrid dynasty with its capital at Samarqand. In 1502 the Safavids established a national dynasty that lasted until 1736.

Architecturally the Islamic (q.v.) epoch is known for its mosques, minarets, tombs, and bridges, most of them built of brick, fired or unfired. Outstanding amongst the structural elements are the dome, the squinch, the pointed arch, and the monumental façade, all of which are found together in the mosque. Chronologically the development is one primarily of elaboration and organization, the earliest mosques having flat roofs on columns or piers, recalling their Achaemenid ancestors, whereas their successors had arcaded courtyards with domed bays. Soon the evolution of the squinch permitted the multiplication of domes and later the center of each side of the arcaded courtyard was pierced with a vaulted īvān, or three-sided room, with a mihrāb, or shrine, at its rear. The whole Islamic era is devoid of sculpture, but its place on buildings is taken by floral designs or inscriptions in stucco and geometric designs and inscriptions in brick. Although the elaboration and forceful modelling of stucco ornament under the Seljūqs (1037-1300) carried it to its height, by about the 12th cent, such strides had been made in the use of enamel tiles and faience mosaic that

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

they were beginning to supplant all other decoration. In these buildings is found the same combination, though in different proportions, of overpowering masses and delicate detail that existed in earlier structures. Honor was done to god and king by the construction of such massive monuments, and the sensitive, sensual palate of the Persian people was pleased with the subtle ornament, the colorful mosaic. The mosque reached its culmination with the building of Shāh 'Abbās (1587-1628) of the great Masjid-i-Shāh at Isfahān, a perfect example of architectural planning and polychrome decoration.

Except for architecture, great religious art died with the Sāsānian Period, for the old tradition had run its course, and the Muslims were opposed to the representation of anything living. Thus, sculpture was supplanted by ornament, and pleasing decorative surfaces took the place of significant symbolic content.

What little is known about Sāsānian pottery points to the fact that it is far inferior to the metalwork, which is hardly the case in Islamic times. For now not only did tile and mosaic ultimately come into their own, but also the Persian love of color and decoration found an outlet in the painting of pottery. The body of the vessels was never as fine and tough as the hardier Chinese wares, since the makers were content to take the material at hand, but the coarse and friable local clays produced an impermanent, porous ware that responded readily to the craftsman's slightest pressure. The resultant output evinces an unfailing sense of ceramic modelling, with delicate curves united with straight lines in just proportion to the requirements of the object. Yet all these things were made for use, and each was suitable to its purpose. All of the early wares are of simple clay, but the finest of the later ones are of a powdered quartz often referred to as faience. As far as material is concerned, there are three main types, almost infinitely divisible: namely, a red ware with slip decoration and a usually colorless glaze; a buff ware with an opaque cream-white glaze decorated in luster or colored glazes; and a white sandy ware with either translucent or opaque glaze and with luster or under- or overglaze decoration. The dearth of material scientifically excavated makes impossible the task of pigeonholing the various kinds, but a few of the main categories follow. The wares of the 8th-9th cent. were splash-glazed in imitation of T'ang dynasty pottery of China, and in the 9th-10th cent. there were white wares painted with dark blue and others painted with luster. From now on engraved, sgraffito carved, and relief decoration persist. The 11th-12th cent. wares heretofore called **Gabri**, with powerful animals and foliate designs relieved in underglaze slip, are now assigned to **Aghkand** and **Yastkand**, whereas the polychrome painted white dishes formerly known as Lakabī are still without a provenience. Also in the 11th-12th cent. luster-painted wares come again to the fore, this time at **Rayy (Rhages)**, followed in the 12th-13th cents. by **Kāshān** and in the 13th-14th by **Sultānābād**. Both Rayy and Kāshān are famous for bowls with large, strong figures painted overglaze, and the potters of Kāshān often added gliding. Throughout the whole period inscriptions played a prominent part on most types, and many dates have been furnished by writings on tiles. The most usual types are bowls, cups, ewers, vases, and tiles. Somewhat in the 13th cent. and more in the 14th, figures and other components of the design began to be multiplied until the shape of the vessel lost its importance. It is true that there are excellent later wares with ethereal, elongated, swaying youths and ladies, but they are too few to impede the decline from the heights.

The earliest Muhammadan bronze and silver vessels made in the 9th-10th cent. were simple and unpretentious, with only slight engraved designs. In the 12th-14th cent. objects were made of bronze, brass, and silver. At first the decoration was confined to engraved Arabic inscriptions, roundels, animals, and foliage, but soon it was broadened to include copper and silver inlay, figures, hunting scenes, etc. The usual shapes for silver were fewer than those for bronze and brass, which took in mortars, ewers, stands (often pierced), trays, kettles, candlesticks, basin, and the like. Some incense burners were in the shape of birds or animals with pierced decoration, and a few of the latest brass ewers were ornamented with birds and animals in the half-round or round. As in the case of ceramics, the 14th cent. was the signal for the decline in metalwork. Subsequently a handful of fine candlesticks, basins, etc., was produced, but the elaboration of the ornament at the expense of the shape was not long in taking its toll.

Under the Muslims textiles continued to be of the utmost importance, the earliest being dated tentatively in the 10th cent. and carrying on the Sāsānian tradition of paired birds and animals, heraldic beasts, and roundels arranged in a rigid pattern. The same motives were employed by the Seljūqs, but geometric rigidity gradually gave way to all-over pattern

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

with a broken field, resulting in an elegance admirably suited to silk textiles. In the 13th-15th cents. under the Mongols and the Tīmūrids the earlier regularity was sacrificed completely to a free arrangement of flowing arabesques and floral motives, and under the Safavids in the 16th-17th cents. figures, animals, and flowers were scattered with a luxurious profusion over the whole surface. It was at this time that the cone pattern originated, and stories of Laylā and Majnūn, Khusrau and Shīrīn were interspersed with various other motives. Sooner or later nearly everything was tried: more colors, metal threads, embroideries with animal and hunting scenes, and even a return to the earlier arrangement in stiff horizontal rows. Fine textiles were made well into the 18th cent., for since a textile has little shape to be either strong or weak, the elaboration and softening of the design is not necessarily so deleterious as in the case of metals and ceramics.

Although it is known that Khusrau I (Chosroes) had a large "garden carpet" in the 6th cent., the earliest extant carpets are from the 16th. Fine "Persian rugs" produced in the next two and a half centuries are too numerous to be recorded. In these the pile was usually of wool and the foundation of wool and cotton, but sometimes the pile, and sometimes both pile and foundation, were of silk. In certain types there is an admixture of gold and silver threads. The best-known are the garden carpet, with its crossed water-courses meeting in a central pool; hunting-scene carpets; medallion carpets, in which animals stalk amongst flowers and medallions; vase carpets, with flowers branching from a central vase; and the so-called Polish or Polonaise rugs, of silk pile and often with gold and silver threads.

The absence of early murals leaves obscured the origin of the art of painting in Persia. All that need be said is that the oldest dateable Persian paintings are book illustrations of the early 13th cent. and that there is definite Manichaean influence. The frowns directed towards "frivolous" painting by the Muslim fathers prevented there being a public art, and the Muhammadan prohibition against reproducing any living thing effectively precluded a great religious art. A few "miniatures" have religious subjects, and most show the influence of an undercurrent of Sufi mysticism, but there is nothing comparable to the great paintings of Buddhism and Christianity. The painters were employed by the nobles, who had no scruples against having their favorite manuscripts illustrated. The earliest of these, like the *Kitāb-i-Samak-i-'Ayyār* and the Galen, are distinguished from their more famous Mesopotamian contemporaries by a consciously decorative arrangement of figures and other components against a solid red background. A 13th-cent. copy of the *Kalīla wa Dimna* or *Fables* of Bidpai displays a sympathetic understanding of animals that combines the Persian light-heartedness with a naturalistic approach that is unusual for Persia. In the second half of the 13th cent., after the Mongol invasion, one finds in a MS. like the *Manāfi' al-Hayawān,* Description of Animals, in the Morgan Library, pure Persian pages together with some that show strong Mongol influence and still others that seem to have been painted by Far Easterners. By 1300 the various elements had been assimilated to such an extent that the presence of Mongol features in one instance is taken as much for granted as is their absence in another. Of the former kind is Rashīd ad-Dīn's *Jāmi' at- Tawārīkh* or *History of the World,* in which Mongol types, the nomadic love of space, Chinese clouds and draughtsmanship are synthesized by the Persian decorative sense into pictures of great vigor. All Persian painting is two-dimensional, with no cast shadows and with the high horizon of "bird's eye" perspective, yet the adept use of brush- or pen-strokes to delineate contour gives an adequate suggestion of three dimensions, and the bird's-eye view is in many respects superior to photographic perspective. The subject-matter is anecdotal and legendary, having for the most part been taken from Firdausī's *Shās-Nāma,* or *Story of the Kings,* and from Nizāmī's *Khamsa,* or *Poems.* The former has to do with exploits of legendary heroes and actual kings, such as the great Sāsānian Bahrām Gūr, whose hunting feats are a constant delight, and is beautifully illustrated in a copy made in Tabriz about 1340. From late in the 14th cent. the intrinsic hedonism of the Persians becomes more and more evident through the increased interest in surface decoration at the expense of vitality, and greater elegance and refinement in place of anything actually reminiscent of realism. The most famous name in Persian painting is Bihzād, who, at the end of the of the 15th cent., rose above the prevailing interest in mere decoration and, using a line of the utmost delicacy, imbued his characters with the appearance of sustained motion. He was followed, towards the mid-16th., by a group of men who produced the greatest copy of the *Poems* of Nizāmī, now in the British Museum. The men were Mīrak,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Sultān Muhammad, etc., and the pictures illustrate the loves of Khusrau and Shīrīn, Laylā and Majnūn, and the Ascension of the Prophet Muhammad. By the 17th cent. the old tradition was all but threadbare, and it remained for Rizā 'Abbāsī to try to revivify it. His pictures of single figures such as youths, ladies, dervishes, etc., are remarkable for virtuosity of brush-stroke rather than luxurious of color, but the roots did not go deep enough for the nourishment of the tree, the death of which had been only postponed.

Calligraphy, to the Persian, is a greater art than painting and is found primarily in copies of or extracts from the Qur'ān. Not so profound as the Chinese, where each character not only is capable of being beautifully written but also symbolizes an idea, the Persian has a quality of abstract beauty that gives the effect of a perfect mathematical equation or an exceedingly melodic measure. It can be monumental or graceful, leisurely or impetuous, fluid or staccato. Whether it be the noble, regular characters of the early Kufic or the rhythmically flowing script of the later Naskhi, it epitomizes the Persian's desire for elegant expression. Stylistically and historically it kept pace with the art of painting, finally succombing to the universal appetite for prettiness. See *Ars Islamica,* ed. M. Aga-Oglu, R. Ettinghausen, v.1-9, 1934-42; *Handbook of Mohammedan Decorative Arts,* M. S. Dimand, 1930; *Iran in the Ancient East,* E. Herzfeld, 1941; *Manuel d'Art Musulman,* G. Migeon, 1927; *Persian Art,* ed. **Persian carpet.** A carpet made in one piece instead of in breadths or strips to be joined. The warp and weft are of linen or hemp and the tufts of colored wool are inserted by twisting them around the warp. A line of tufts being inserted, a shoot of the weft is made, and then beaten up close to the fabric.

Persian carpets in structure, design and color are the models on which the whole of the Eastern craft industry has been formulated and developed. Best productions of Turkey and India evince the influence of historic Persian work. The Turkoman has introduced bolder pattern forms executed in standardized red and blue coloring and the Indian craftsman decorative types of a purely national feeling and character, but in each result the design treatment and carpet make are plainly of Persian origin. Chinese and Japanese rugs are of a somewhat different category. The former employ silk yarns freely, and adhere to the art traditions of China in textural surface ornaments; and the productions of Japan are made of cotton and in design schemes largely borrowed from foreign loomwork. *Identification.* In the three kinds of weavings in oriental rugs, the Khilim, the Soumak and the rug with the pile are produced over one hundred different kinds of rugs named after the towns and districts in which they are made and after the people who made them. These are identified by innumerable details of design, material, construction and finish. See Persian Art, also A. U. Dilley, *Oriental Rugs;* W. R. Valentiner, *Early Oriental Rugs;* A. F. Kendrick and C. E. C. Tattersall, *Fine Carpets in the Victoria and Albert Museum;* J. F. Ballard, *Oriental Rugs;* C. R. Clifford, *Rugs of the Orient;* M. S. **Persian knot.** See ISLAMIC ART; Sehna knot.

**Persian porcelain.** See CERAMICS II.

**personification.** See allegory.

**PERSPECTIVE** (L. *perspectiva*). That which suggests the effects of distance upon the appearance of objects.

**Aerial perspective** concerns effects of distance upon the color and distinctness of objects. The air, especially when hazy, makes far objects appear bluer, grayer, less distinct in edges and with less contrast of light and shade than if seen nearby. There are no definite rules; skill depends upon experience in observation of nature, beginners tending to ignore such effects and paint the distance of a picture too much like the foreground. (See **constancy** under PSYCHOLOGY OF DRAWING AND PAINTING.)

**Linear perspective** pertains to effects of distance upon the appearance of size and form; e.g., in a typical view down a railroad track the rails and telegraph wires appear to converge to a **vanishing point** on the **horizon,** the successive sleepers and poles seeming to be progressively smaller and closer together as they recede into the distance. Such apparent diminuation of these intervening spaces because they are seen from an acute angle is called **foreshortening.**

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Perspective is chiefly used in pictures, but it sometimes occurs in three-dimensional art. In sculptured reliefs it can be employed much as in pictures. In a cyclorama (q.v.), the third dimension usually ranges in transition from full scale in the foreground through progressively reduced scales in the middle distances to a pictorial background which is practically two-dimensional in treatment even though its surface may be curved. Stage settings (q.v.) are often somewhat similarly designed. In landscape architecture (q.v.) the apparent depth of views can be increased by causing foreshortened lines on the ground which one would expect to be parallel to slightly converge, by having irregular instead of straight boundaries in masses of foliage, and by using materials in the distance which are small in size, fine in texture and bluish in color, contrasted with foreground features having opposite qualities.

It is probable that this illusory property of color is due not only to the simulated aerial perspective, but also to the psychological phenomenon of **retreating and advancing colors.** (See COLOR.) Corresponding influences also occur in architecture and interior decoration. Some artists have experimented with such colors for inducing an effect of solidity in paintings, but we are chiefly dependent on linear perspective for suggesting depth in pictures.

The basic principle by which a flat picture can represent a three-dimensional object is that of **radial** or **conical projection.** The artist or **spectator** is conceived as using only one eye and keeping it strictly in one position called the **station point.** He sees the object because **visual rays** of light, forming a **visual cone of rays,** pass from the various parts of the object into his eye. If a pane of glass (**picture plane,** theoretically of indefinite extent) were held rigidly and squarely across the approximate central **axis** of this cone, the spectator could trace lines on the glass coinciding with the edges of the object as he sees them and thus preserve a record of his view, a picture. In actual practice the equivalent of this situation is usually produced artificially by means of various geometric devices, on paper.

When a rectangular object, such as a box, is level and its receding edges seem to go toward one vanishing point which is directly in front of the spectator at his eye level, like that of the rails and wires in the previous example, while its other level edges are parallel to the bottom of the picture, it is said to be in **one point** or **parallel perspective.** This vanishing point in such a case is called the **center of vision.** If the box, though still level, is turned so that its sides are at other angles to the picture plane, they will seem to vanish at two widely separated points on the horizon, and it is described as being in **two-point** or **angular perspective.** Any vanishing point of a line representing an edge of an object can be located on the picture plane by imagining that the spectator looks in a direction parallel to the edge, and noting where his line of gaze, called a **vanishing parallel,** intersects the picture plane. The imaginary path, seemingly in the infinite distance, followed by the vanishing points of level edges as the box is turned, is represented on the picture plane by a line termed the **horizon line,** and all vanishing points of level edges, no matter how high or low, are on it. It is always at the level of the spectator's eye, practically coinciding with the visible horizon where sea or plain and sky seem to meet—the difference between them, due to the earth's curvature, being negligible at usual altitudes. In both parallel and angular perspective there is so little convergence in the vertical edges of the object that it is ignored. The picture plane is considered vertical. If a box is tipped, or is seen from such an angle that there is evident convergence in all its edges and conceived as seen through an inclined picture plane, it is said to be in **three-point** or **oblique perspective.**

If a box in parallel perspective has a partly opened lid hinged on one of the receding edges, the lid will have a special horizon line of its own, called a **vanishing line,** passing through the center of vision and tipped to the same angle as the lid. If a rectangular object, like a ruler for instance, is laid on the lid so that its long edges are foreshortened but not parallel to any edges of the lid, the ruler edges will vanish on the vanishing line at some point other than the center of vision. If the lid is hinged on the nearest top edge of the box, as the lid is opened its vanishing point will rise from the center of vision to points higher and higher directly above. Likewise, if the lid is hinged on the farthest top edge of the box, its vanishing point will go directly below the center of vision in proportion to the amount the lid is opened. Such vanishing points off the horizon line are called **accidental vanishing points.** The imaginary vertical paths followed by these points form a vanishing line

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

for the imaginary planes generated by the right and left sides of the lid as it moves. If the lid is held in some sloping position and the ruler is laid across it, any foreshortened edges of the ruler will vanish at a horizontal vanishing line passing through the accidental vanishing point of the lid. If the box is in angular perspective, and if, for instance, its hinges are on its nearest right edge, when the lid is raised the sloping edges of the lid will vanish at an accidental vanishing point exactly above the left vanishing point. A ruler laid across the sloping lid would have its accidental vanishing points on a vanishing line which would pass slantingly through both the accidental vanishing point of the lid and the right vanishing point of the box.

Curving or irregular edges have no vanishing points, but can be put into perspective by locating points at selected places on them, then sketching freehand the parts between those points.

There are several methods of locating points in a perspective drawing. In the **direct projection** method a **plan** (q.v.) and a **side elevation** (q.v.), each showing the object, the picture plane and the spectator, are drawn, then visual rays are ruled connecting the station point with all important points on the object which would be visible to the spectator under the conditions, and the intersections of the rays with the picture plane are noted. The picture plane's plan and side elevation containing the notations of these intersections are finally combined by **orthographic projection** (q.v.) in a front elevation of the picture plane, which constitutes the picture. This method is used chiefly by architects, since they have plans and elevations of their subjects available, which usually is not true of painters. However, the most interesting views of buildings generally are in two-point or three-point perspective, and this process in such cases involves constructing oblique side elevations, each combining two façades. To avoid this labor the **mixed method** is more commonly employed, in which visual rays from the plan view only are projected to form a perspective view of the ground plan of the object, then the heights are usually measured by reference to one or more scales of heights or **height lines**, erected on the **ground line**, which is the intersection of the picture plane with the **ground plane**, the level ground on which the object is customarily assumed to be standing. (If an object is actually on sloping ground the perspective is worked first on this artificial level plane, then the irregularities in the ground are constructed, usually like combinations of more or less wedge-shaped objects, the junctions of which are later rounded to natural forms by freehand drawing.) Two upright spaces of the same size and on the same level, like the heights of two fence posts, for instance, can be drawn the proper comparative height in a picture by imagining them to be connected by parallel lines at top and bottom and putting these lines into perspective. Addition or subtraction of heights can be done by direct measurement on vertical lines in parallel or angular perspective since upright edges are not noticeably foreshortened in such views.

There is often considerable practical difficulty in working by projection of visual rays because of inaccuracy and confusion of lines when many details are involved, so other methods less direct in theory but simpler in execution are frequently employed. Many of these depend on the general idea of relating the points whose location is required to some combination of parallel with diagonal lines which can be conveniently put into perspective, since diagonals of parallelograms function the same way in views which are foreshortened as in those which are not. The simple crossing of diagonals gives the center, and a line passing through this crossing, parallel to one of the sides, cuts the adjacent sides in halves; these divisions can themselves be divided likewise and the process continued to any degree of subdivision desired. Conversely, parallelograms can be multiplied indefinitely by extensions of their sides and diagonals, each space being treated as half the succeeding space. A line parallel to the lengthwise edges of a row of equal rectangles will cut all parallel diagonals in the series at corresponding places, then a line in each rectangle parallel to the other edges will carry the location to any desired distance across the row, these crosswise lines being cut off uniformly by another lengthwise line. This provides the same kind of unequal subdivision in all the rectangles at once and saves much time in drawing repeated details. A similar combination of lengthwise and crosswise lines when made to cut *opposite* diagonals in a single rectangle will provide a symmetrical arrangement of points within the rectangle—or of points outside the rectangle if the diagonals are extended beyond their corners.

Diagonals of squares are especially useful because they cut off equal distances on crossed

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

lines extending in two directions perpendicular to each other. For example, if an equal border or overhang is desired around a foreshortened rectangular space, it can be made by drawing an imaginary square of fairly large size with its sides perspectively parallel to the sides of the rectangle (or perhaps in part coinciding with them), correcting its proportions until it looks fully satisfactory, then extending its more foreshortened diagonal to a vanishing point, called a **miter point** in such a case. This can be used also for the corresponding diagonal of a smaller square which can be made at each corner of the rectangle, thus making all four small squares consistent in proportion, while extensions of their sides can make them consistent in size and produce the desired border or overhang. Mouldings can be turned around corners by similar means, with perpendiculars, indicating the amount by which each important part projects from the base, placed on the diagonals and compared by means of perspectively parallel lines at the top and bottom of each perpendicular.

Irregular or curved patterns, such as might occur on a map or in a floor plan or wall elevation of a furnished room, can be put into perspective by making a network of squares over the pattern, drawing this net in perspective with corresponding diagonals vanishing at a single point, then sketching freehand the forms that fall within each square. This is called the **method of squares.** It is most easily managed if the squares are in parallel perspective, since this brings the vanishing points of their diagonals, called **points of distance** in this case, to the same distance from the center of vision as the station point.

The labor of making a complete network of squares can be saved and precision gained by arranging, in effect, that each point requiring accurate location shall be in turn at a corner of a single special imaginary square of its own, extending between the point and the picture plane. In other words, distances on the ground plane which are perpendicular to the picture plane can be measured, even though foreshortened, by setting off corresponding spaces on the ground line and transferring those lengths to the foreshortened line by means of lines vanishing at a point of distance.

Likewise, foreshortened distances in other directions can be measured by utilizing the geometrical principle that lines parallel to the base of an isosceles triangle cut off equal lengths on the opposite sides. In practice this is done by drawing a plan view of the picture plane and station point, and also the vanishing parallel and vanishing point of the line to be measured; usually this plan view is superposed on the perspective view, the line representing the picture plane being made to coincide with the horizon line, while the plan of the object is omitted. An arc with the vanishing point as center is swung from the center of vision to the horizon line, which it intersects at a point called a **measuring point.** An imaginary vanishing parallel to this latter point would complete a plan view of an isosceles triangle. A similar triangle, foreshortened, is formed on the perspective with (1) the ground line, and (2) any line drawn from the ground line to the vanishing point, as sides and (3) any line drawn from the ground line to the measuring point as base, setting off perspectively equal distances on the other two lines. Thus direct measurements on the unforeshortened ground line can be transferred to the foreshortened second line. This procedure is the basis of what is known as the **perspective plan** method.

If the line normally drawn to the measuring point is drawn instead to a point called a **half measuring point,** situated half-way between the measuring point and the vanishing point, the distance measured will be doubled. Use of a **quarter measuring point** quadruples the distance, and corresponding results ensue with other fractions and with points of distance. Thus long foreshortened distances can be measured without extending the ground line beyond convenient limits.

It frequently happens that the level of the ground at the base of an object is so near to the spectator's eye level that there is considerable danger of inaccuracy because lines in the perspective plan are crowded and intersect at very acute angles. This can be avoided by assuming an artificial base at a much lower or higher level, making a **sunken** or **raised plan,** and transferring data from one level to the other by means of vertical lines. In such a case the measuring of horizontal distances is done mostly on an artificial ground line or **picture line** beneath or above the normal ground line and parallel to it.

Distances on lines oblique to both ground and picture planes can be measured by conceiving that the line is contained within a vertical or an oblique plane, and finding by various geometric means: (1) the vanishing

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

line of that plane; (2) the **center of the vanishing line**, the point on the vanishing line which is nearest to the eye and the center of vision, and which serves as a special center of vision for that vanishing line; (3) a special plan or elevation view of the eye or station point as related to the vanishing line; and (4) the trace or line marking the intersection of the vertical or oblique plane with the picture plane as represented by the ground line. This trace is always parallel with its vanishing line, and is called the "picture line" of its vertical or oblique plane. Now accidental vanishing points for the original line and for other lines in the same plane at any desired angle to the first line are located by means of vanishing parallels; and measuring points for each accidental vanishing point can be found and used in the same manner as that described in connection with angular perspective.

In practical use perspective frequently needs to be worked backwards by means of an **inverse process.** The artist makes a rough freehand sketch embodying about what he wants for a result, and his problem is to discover what minimum adjustments may be added in order to make this sketch represent a reasonably possible arrangement of real objects. Sometimes also it is necessary to learn the relative actual proportions of an object in a photograph.

The first step usually is the extension to vanishing points of any lines in the picture which clearly represent parallel receding edges. If these are evidently level their vanishing points should be on a single horizontal line. If any of the vanishing points are **conjugate** (belonging to edges obviously perpendicular to each other) a semicircle can be drawn between those vanishing points, and the station point must needs be somewhere on that semicircle, since the vanishing parallels of perpendicular lines form a right angle at the station point and only right angles can be inscribed within semicircles. A line used for such a purpose as this arc is called a **locus** (pl. **loci**). If the object is in oblique perspective there are three loci which are conceived as generating three hemispheres; the one point common to all three is the station point. This can be located for practical use by: (1) connecting the three vanishing points with their vanishing lines, thus forming a triangle which constitutes the base of an imaginary pyramid whose apex is the station point and whose sides have right angles at the apex; (2) finding a plan view of this apex by drawing a line from each vanishing point toward, and perpendicular to, the opposite side of the triangle, then noting where these perpendiculars intersect; (3) revolving the station point thus found into the plane of the picture by projecting it to a semicircular locus with any desired one of the vanishing parallels as a diameter, using for the projection a line perpendicular to that vanishing parallel. If the object is in angular perspective the station point is found by (1) drawing freehand with care a fairly large square, whose sides vanish at the vanishing points of the object; (2) extending the more foreshortened of the diagonals of this square to its miter point; (3) continuing the semicircular arc to a point directly above its center, thus making three-quarters of a circle; (4) drawing a line from the last-mentioned point through the miter point until it crosses the arc below; this intersection is the station point, since only a 45° angle can be inscribed within three-fourths of a circle and this is the only point which will at once satisfy the requirements of both lengths of arc. If a photograph instead of a sketch is being analyzed the center of the untrimmed print can be assumed to be in a vertical line with the center of vision and the station point thus derived. A sketch in parallel perspective of course reveals its center of vision directly; its distance points can be readily obtained by extending the diagonals of a carefully drawn freehand square whose foreshortened edges vanish at the center of vision.

Returning to the example given earlier of a view down a railroad track, it is clear that since the width between the rails is constantly diminishing in the picture as the track recedes, there is a choice of many possible scales at which to work in comparing that width with other distances. If a given plan or end elevation of a locomotive were to be put into perspective it would be easiest to do so by finding the place on the track in the perspective where the width between the wheels in the plan or elevation would exactly fit, and doing all measuring—i.e., erecting a **plane of measures**—at that point. In dealing with any object similar use can be made of pairs of lines receding to any vanishing point for the purpose of transferring heights, or to pairs receding to measuring points measuring spaces on lines in angular perspective. Thus a plane of measures can be assumed at any depth within a picture which is convenient, either

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

in front, behind or passing through the midst of objects. Some writers identify this plane of measures with the picture plane; others distinguish between them and conceive the latter as being like a window through which the scene is viewed, hence always between the spectator and the nearest object.

Of more importance than this question of terms is the adaptation of the perspective in a picture to the distance from which it will be seen. Assuming that the picture plane coincides with the surface of the picture itself, the length of the **line of direction** (the line between the center of vision and the station point) should be about the distance from which the picture is most likely to be viewed. For instance, for a book or magazine illustration this should be about 14 inches—the average reading distance—, for a painting to be hung on a living room wall, considerably more. The inconvenience of using widely separated vanishing points frequently stimulates a placement of them too close together, resulting in **violent perspective.** Sometimes a certain amount of violence is justifiable for sake of expression, since it gives an effect of intimate closeness to the objects, but it should not be permitted for any less important reason. There are various aids available for obviating the difficulties of widely separated points. Among these are the **centrolinead,** a mechanical device resembling a T square for making converging lines, and the **half station point** (located at half the distance of the true station point from the center of vision) which can be used in the same way as the true station point for placing its special vanishing points and measuring points, then the distances of these points from the center of vision can be doubled and the corresponding true points obtained.

Distortion is also caused if too wide a space is included in the picture. The visual cone of rays should certainly not have at its vertex an angle larger than 60°, and results are better if it is 30° or smaller— especially if the picture contains round objects near its edges, as the distortion is particularly noticeable in such cases. Sometimes it is wise to avoid such effects by using **curvilinear perspective,** in which the picture plane is treated as if cylindrical, or, more rarely, spherical.

**Freehand perspective** or **model drawing theory** is usually treated as essentially an informal sort of curvilinear perspective in which each object is drawn freehand independently of the others in the picture except those to which it is very near, the picture plane for each being perpendicular to an imaginary line drawn from the eye to the approximate center of each object or group of objects. It deals especially with the perspective of the structural relationships between the parts of each object, and gives relatively little emphasis to the comparative sizes and other relations of objects to each other and to the world at large.

*Shades and Shadows.* Perspective considerations apply also to the drawing of **shade** (darkness of certain areas on objects caused by those parts being faced away from the source of light) and **shadow** (darkness due to light being cut off by some intercepting material). Light travels in straight lines radiating from its source in all directions. This radiation is evident with artificial illuminants near at hand; but the sun and moon are so far away that their rays are treated as parallel, with vanishing points at either those bodies themselves or at points directly opposite them—depending on which way the spectator is facing.

The **base** of a point on a plane is at the place on that plane which is nearest to the point. The typical process of locating the shadow of a given point follows: (1) the base of the point is found on the plane which will receive the shadow; (2) the base of the light source or of the vanishing point opposite the source is found either on the plane itself if the source is artificial or on the horizon or vanishing line of the plane if the source is the sun or moon; (3) a line is drawn from the latter base through the given point's base; (4) a line representing a ray of light is drawn from the source, or from the vanishing point opposite the source, through the given point. The intersection of these two lines, or of their extensions, is the desired shadow of the given point.

It is not necessary, however, to find bases on all planes receiving shadows, since shadows are readily carried from one surface to another, and it is usually most convenient to do all the work with bases only on the ground plane. For illustration, let us suppose that a plumb line is dropped from the given point to the ground. This string, because of its interruption of the light flooding past it, might be conceived as generating in space on its side opposite to the light source a plane of potential darkness which only becomes visible where some other object crosses through it, making a shadow of the string which is

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

cast on the lighted parts of the object wherever the plane intersects those parts. The shadow of even a complex object can be found, if the perspective plan of the object is available, by thus dropping an imaginary plumb line from each important point on the object to its base on the ground or on some other horizontal plane, finding the shadow of each string, then drawing lines connecting the ends of these shadows.

The points on an object which are important for shadow projection are those which are on the boundaries between its lighted and shaded areas, where the rays of light are tangent to the surfaces of the object. These can be found by use of series of imaginary slices or **cutting planes** conceived as passing through the object.

*Reflections.* Perspective also occurs in reflections. Reflected light rays obey the same law as all rebounding bodies: the angle of reflection is equal to the angle of incidence. This causes the reflection of a point to seem to the spectator to be located as if on an imaginary line perpendicular to the reflecting surface, the same distance beyond its base on the surface as the point itself is from the base. This implies that the reflection of a three-dimensional object is by no means a mere replica in reverse of the appearance of the object, as many suppose, but needs to be constructed point by point. It often happens that the object reflected is not in direct contact with the reflecting surface—as, for instance, when the spire of a church in the middle distance is reflected in a pool of water in the foreground. In such case the reflecting surface should be imagined as extended to include the base, as if the intervening material were not there—although the latter may have its own reflection too, for which provision must be made. If an edge of a reflected object is parallel to the reflecting surface the reflection is parallel to the edge. Reflections in water are distorted and broken if there are waves, whose numerous facets transmit fragmentary images from many directions, often with beautiful effects of both shape and color.

*Refraction.* When a ray of light which has been passing through one medium, such as the air, enters obliquely a denser medium, such as water, the added resistance causes it to be somewhat bent from its course. The amount of this **refraction** in water is such that an immersed object appears to be at approximately only three-fourths of its true depth.

*History of Perspective.* It is difficult to say when the use of perspective began. While primitive men, like modern young children, have always preferred to represent each object in a scene as clearly separated from its neighboring objects, very early in the development of mankind artists began to show one figure as partly hidden behind another, both being in elevation, often supported by a straight line to represent the ground. More distant objects were drawn on a higher level, sometimes standing on another ground line, sometimes not. The diminution of size with distance has been of considerably later development, early artists frequently using size as an indication of relative importance rather than of distance.

Many modern oriental artists, due to a deeply subjective attitude toward art as a mode of spiritual expression in which resemblance to literal objective appearance is of slight importance, coupled with a strong reverence for tradition, have continued to the present day a use of linear perspective somewhat resembling these primitive types—although their employment of aerial perspective is often comparatively realistic.

Probably one of the first books on perspective was written by Agatharchus, an Athenian of the 5th cent. B.C., who also, according to Vitruvius, was the first to paint scenery for the drama. Paintings preserved on the walls of Pompeii reveal remarkable skill of Roman artists in the use of parallel perspective.

In the Renaissance the scientific study of perspective was rapidly developed by Paolo Uccello, Leonardo Da Vinci, Albrecht Dürer and many others. The enthusiasm which was felt in those days for producing illusions of depth is revealed by the emphasis in many pictures of that period upon architectural vistas and like subject matter, and by the admiration recorded by the contemporary writer, Vasari.

Familiarity with angular perspective was a comparatively late development, and oblique perspective later still. Indeed the latter has only recently begun to be used extensively, no doubt as a result of the advent of the skyscraper and the increase in air travel. It is probably in this field that we may expect the chief developments of the future.

*Terminology.* There has been an unfortunate lack of standardization in the use of perspective terms by the writers on the subject. Lists of synonyms follow in which terms employed by at least two authors are given in approximately the order of pre-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

dominance of usage. Those about which there is general agreement and which already have been explained are omitted.

**Station point** (the spectator's position), *point of sight* (used by other writers as meaning *center of vision*), *eye, point of view.*

**Line of direction** (the spectator's orientation, fixed by a line from him perpendicular to the picture plane), *principal visual ray axis, line of sight, central visual ray;* (orientation fixed by a line through the station point parallel to the picture plane), *directing line.*

**Distance of the picture** (the spectator's distance from the picture plane).

**Cone of rays** (the spectator's range of view, in terms of angle), *visual angle, visual cone, scope of vision;* (in terms of diameter), *field of view, base of cone of rays.*

**Picture plane** (the theoretical transparent surface of the picture), *plane of delineation, plane of the picture, perspective plane.*

**Ground line** (the intersection of the picture plane with the ground plane), *picture line, base line.*

**Picture line** (the intersection of the picture plane with a plane other than the ground plane, used for measuring purposes). (There is no synonym for this general concept which has been given substantial usage. The term is mentioned here to distinguish it from its use by other writers as a synonym for *ground line*).

**Horizon** or **horizon line** (the imaginary line containing all vanishing points of level lines), *horizontal line.*

**Center of vision** (the vanishing point of lines perpendicular to the picture plane), *point of sight* (used by other writers as meaning *station point*), *center of view, center of picture, principal vanishing point.*

**Point of distance** (a measuring point for lines perpendicular to the picture plane), *distance point.*

**Miter point** (a vanishing point for lines at 45° to a pair of mutually perpendicular lines in angular or oblique perspective) *vanishing point of diagonals.*

**philosophical aesthetics.** See AESTHETIC INQUIRY, CURRENT TYPES OF.

**PHILOSOPHY OF ART.** In order to determine the purpose of a philosophy of art, we must distinguish it from aesthetics. The relation between the two fields admits of divergent interpretations which fall into three main types. (*a*) We may deny the validity of the distinction and regard the two terms as synonymous—the view espoused, e.g., by Benedetto Croce and his numerous followers.[1] In this as in other cases Croce's bold simplification tends to cover up the complexity of the problem. (*b*) Aesthetics, the philosophical analysis of *beauty,* may be distinguished from the study, philosophical or otherwise, of *art* as a form of human productivity. In this view the two fields overlap without being coextensive. Although there is an important relationship between beauty and art, not all works of art, it is pointed out, purport to be beautiful. This dualistic notion sprang from a desire to emancipate the luxuriant growth of the modern study of art in its various aspects (sociological, anthropological, psy-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

chological, and so forth) from the tutelage of a conservative and classicistic aesthetics. It is reflected by the double-barrelled title of the most important periodical in the field, the *Zeitschrift für Ästhetik und Allgemeine Kunstwissenschaft*, founded by Max Dessoir in 1906.[2] Dessoir's contention may be countered with the remark that "beauty" should be conceived more broadly, not merely as denoting the harmony of formal organization or crystalline perfection but as encompassing the tragic, the grotesque, and the harshly realistic forms of art.[3] Once this is admitted, the strongest argument for the separation of the study of art from aesthetics loses its force.

(*c*) While conceding to aesthetics the traditional privilege of covering the whole area of both beauty and art, account may be taken of the natural difference between the word "aesthetics" which indicates receptivity and "art" with its emphasis on production. Accordingly we may mark off within aesthetics a sector more specifically devoted (I) to the problems of art as a type of human productivity, (II) to the study of the relations between the multiple arts, and (III) to the location of art within human life. Labelling this triple branch of aesthetics "philosophy of art", we need not claim for our convenient distinction a more than pragmatic validity. This view was adopted for the following survey.

(I) In the mind of modern man, art as comprising the "fine arts", architecture, music, and poetry as well as the so-called minor or applied arts, is clearly set off against other forms of "making" such as manufacturing processes or craftsmanship. This way of grouping the facts has no parallel in the ancient civilizations. The Chinese classified drawing and painting as a part of calligraphy;[4] and the lists of arts found in Indian literature embrace every kind of skilled activity, from music to horsemanship and cookery, ascribing to all an angelic origin.[5] The Greek thinkers to whom we owe the fundamentals of a philosophy of art were equally unacquainted with our narrower, specificially "aesthetic" notion of art, and the same is true of the medieval philosophers. John Ruskin and William Morris forcefully recalled the abiding value of what their contemporaries considered an obsolete approach. The Arts and Crafts Movement initiated by Morris tried to counteract the deleterious consequences which attended the modern point of view. By overemphasizing the distinction between artist and artisan, modern man bade fair to wrench art from its source in sound craftsmanship. As a result, beauty, esoteric and effete, retreated into museums, and the modern home became filled with useless gimcracks and poorly designed utensils.[6] Recently the admirers of medieval craftsmanship found an unexpected ally in John Dewey who decried the division between art and craftsmanship as the relic of an antiquated class distinction.[7]

Aristotle, elaborating on notions inherited from Socrates and Plato,[8] defined art (*techne*) as "a capacity to make, involving true reasoning".[9] It is distinguished, on the one hand, from routine activities which, though productive, are guided by instinct or ingrained habit rather than by reason. The artist knows the purpose of the object which he makes, and he is able to choose the means towards it in an "artistic", i.e., rational, fashion. On the other hand, art as making is distinguished from action. The value of artistic production resides wholly in the work; whereas the appraisal of action must reckon in the agent's motive. Action, ruled by practical wisdom, is inseparable from the acting character. Production, guided by art, issues in a work which has an independent existence of its own. These basic distinctions were bodily taken over by St. Thomas[10] and have been recently revived by the neo-Scholastics.[11]

The attempt to apply the notion of art as rational production to "aesthetic" creations, especially to poetry, encounters a peculiar difficulty. The artist in the Platonic-Aristotelian sense of the word should be able to give a rational account of his work. But the poet is not. He conceives his song in a fine frenzy. When questioned about the poetic art, there was, according to Plato, "hardly a person present who would not have talked better about their poetry than the poets did themselves".[12] An irrational type of production, it seems, does not admit of a rational explanation.

Aristotle contrived an escape from the Platonic dilemma. His *Poetics* reconciled the conflicting claims of inspiration and rationality. Thus he carved the way toward a philosophy of art in the modern sense of the word, opening a long procession of kindred works on the *ars poetica* from Horace down to Boileau and Robert Bridges, and setting a model for treatises on architecture, painting, and music.

The poem, according to Aristotle, is designed to arouse an emotive response—that par-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

ticular emotion which is appropriate first to poetry in general, then to a specific *genre* of poetry such as tragedy or comedy. So the end or purpose, the corner-stone of all rationality, is clearly defined. This end is to be achieved by a representation of life through language. The maker of the linguistic image of life must have a knowledge of life, not of its historical factuality (this is the chronicler's knowledge) but of its ideal possibilities. He shows human actions as they might have happened.[13] Thus poetic rationality, conceived as an analogue to philosophical insight, is made to approach the dignity of inspiration. At the same time, divine inspiration is called down from its Platonic heaven and harmonized with reason. According to Aristotle, the talent of the poet consists in his "ecstatic" or "euplastic" nature, i.e., in his aptitude to be "outside himself" and to slip, as it were, into his characters, living their lives and feeling their emotions.[14]

The limitations of their metaphysical vision prevented the ancient philosophers from developing their studies of poetry and music and of the nature of images and imitation in general into a systematic philosophy of aesthetic creation. In Plato's *Timaeus* the universe is viewed as the work of a divine artificer. This notion of the world as made, implying as it does a dualism of a rational form or model and an irrational stuff, was supplanted in the Christian era with the idea of the world as created, called out of nothing into being by a Divine act. Only after a long and tortuous development did the new metaphysical premiss transmute the ancient theory of rational making (*techne, ars*) into a theory of human creativity, i.e., a modern philosophy of art. Its germs may be traced in St. Augustine, in St. Thomas, in the aesthetics of the Renaissance, in Vico, Shaftesbury, Dubos, Batteux, and Herder. But it reached its climax as late as at the turn of the eighteenth and nineteenth centuries in Kant, Shelling, Hegel, Schleiermacher, Schopenhauer, Coleridge, Ruskin, Carlyle, and Emerson. For these thinkers, art is the work of Imagination, the human faculty which, in Coleridge's words is "a repetition in the finite mind of the eternal act of creation in the infinite I AM".[15] Although today the majority of theorists disown all speculative or theological implications, the influence of the metaphysical idea of imagination is all-pervasive. It is clearly marked in the empathy theory, in Roger Fry's and Clive Bell's notion of the "significant form", in Samuel Alexander's "constructiveness", in Benedetto Croce's "intuition-expression", in I. A. Richards' analysis of poetry, in the functional theory of architecture, and in Jacques Maritain's aesthetic. The latter may be described as an attempt to broaden the Aristotelian-Thomistic notion of *techne* so as to cover the idealistic concept of imagination or human creativity.

Divine creation proceeds from the whole to the parts, from the prototypical forms to their particularized embodiments. Similarly the artist, instead of compounding given elements after a rational schema, unfolds a creative conception. This germinant Idea of his work reflects a vision of the totality of life. Human creativeness appears as the infinitely inferior image of the Divine fiat, holding an intermediate rank between true creation and purposive making. The artist is not a slavish imitator of the appearance of things. But in order to express their formative nisus in living images, he must first, as a faithful observer, subject himself to the factuality of appearance. Likewise, the artist's material, marble or pigments or sounds, is not a foreign matter to be subdued by the mind's tyrannical vision, but a natural affinity must link the mental concept with a material substratum. Nor, on the other hand, is the statue dormant in the slab of marble as the oak-tree is the acorn. The artist cannot substitute his work for the work of nature. But the limited creativity of the human mind has to be released by experience, that is, by the fructifying contact with both the world of created forms in nature and a malleable stuff.

While doing and knowing form two separate classes of human acts, the Divine creation is cognition irrefragably united with production. In an analogous way, artistic creation, though belonging to the active rather than to the contemplative life, involves an intuitive grasp of the essence of things. This cognitive element is so intimately entwined with its imaginative externalization that it can never be wholly segregated and expressed in concepts. The artistic intuition demands a local habitation and reaches maturity only through incarnation in a work. Art is not metaphysics expressed in sensuous forms. But it points towards metaphysical truth; in Schelling's words, it is "the organon of philosophy".[16] In the knowledge of essences, approximated but never fully attained by man, the knowing mind *is* the known object. In a corresponding fashion, the artist transfers himself into the object and, in a measure, becomes one with it. This union of the creative mind

But the limited creativity of the human mind has to be released by experience, that is, by the fructifying contact with both the world of created forms in nature and a malleable stuff.

While doing and knowing form two separate classes of human acts, the Divine creation is cognition irrefragably united with production. In an analogous way, artistic creation, though belonging to the active rather than to the contemplative life, involves an intuitive grasp of the essence of things. This cognitive element is so intimately entwined with its imaginative externalization that it can never be wholly segregated and expressed in concepts. The artistic intuition demands a local habitation and reaches maturity only through incarnation in a work. Art is not metaphysics expressed in sensuous forms. But it points towards metaphysical truth; in Schelling's words, it is "the organon of philosophy".[16] In the knowledge of essences, approximated but never fully attained by man, the knowing mind *is* the known object. In a corresponding fashion, the artist transfers himself into the object and, in a measure, becomes one with it. This union of the creative mind

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

with reality, described as *Yoga* by the Indian thinkers,[17] formed the basis of the Greek *Mimesis* (or imitation) theory.[18] "Who paints a figure, if he cannot be it, cannot draw it", Dante said.[19]

As the order of the sensible world reveals the "vestiges" of the Godhead, the human creator must follow in the footprints of the universal Creator. Thus his work becomes a microcosm. But while reflecting the universal order, it transfigures it in the crucible of an individual mind. Hence the work of art is expressive in a dual sense: it expresses both a total order and the grain and fibre of the mind from which it sprang. This unique imprint with which every artist marks his work is called its style. Since the individual conceives and executes his work as the beneficiary of an artistic, religious, and intellectual tradition, the work exhibits the style not only of a personality but also of a culture, a period, a nation, or of a local artistic school. In this sense we speak of a Greek style in sculpture, of Baroque architecture, of a typically French art, or of the Umbrian style in painting. The notion of style as first developed by J. J. Winkelmann and Friedrich Schlegel gave rise to the modern conception of a history of art. It opened the eyes of historians to the fact that, aside from both the succession of schools and artists and the accumulation of technical experiences and contrivances, there existed an historical continuity which concerned the substance of art: a metamorphosis, a waxing and waning of the artistic vision. Style, expressive of the creative mind and its modifications, is to be distinguished from manner, which is a mode of procedure or treatment. One may copy Michelangelo's manner as Vasari and others did. Style is inimitable. The attempts to resurrect the Grecianor pre-Raffaelite style had to begin with reviving the Hellenic spirit or medieval piety. The desire to be primitive in mind gave rise to artistic primitivism. Before becoming *what* he represents, the artist must be *how* he represents it; in Buffon's words: "The style is the man himself".[20]

(II) The idealistic notion of imagination as human creativity revealed art as a unified realm and thereby stimulated a closer scrutiny of the interrelations between the arts. Comparative studies of arts or groups of arts had been made earlier. Lessing, developing an idea of Abbé Dubos', had distinguished between arts of temporal succession such as poetry and music on the one hand, arts of spatial simultaneity such as sculpture and painting on the other. It had seemed to him that the two different systems of signs entailed different procedures and different objects of representation, bodies forming the natural subject-matter of painting, actions, of poetry.[21] Kant had found the clue to the division of the arts in the triple nature of expression by word (arts of speech), gesture (figurative arts), and sound (music),[22] Herder in the diversity of the human sense-organs.[23] But only for the full-fledged idealistic philosophy of creation did the natural system of the arts become a central problem.

If we regard artistic creation as an analogue to cosmic creation, we may expect the realm of arts to mirror the scheme of the created world. According to Schopenhauer, architecture reveals the idea of crude matter, its gravity and rigidity, landscape gardening the stillness and growth of vegetative life, the figurative arts and poetry the spirit of humanity, and the creative world-ground itself becomes sound and rhythm in music.[24] Schelling and other idealists followed a similar pattern. At the same time they construed the history of art as the temporal companion-piece to the timeless system of the arts. Hegel taught that at the inception of art in the ancient Orient the Idea was still groping after an adequate incarnation. Architecture, uncouth and grandiose, provided the fittest language for this stage of heroic infancy. With the attainment of the Classic Grecian style the marriage of Idea and Form was consummated and gave birth to sculptural perfection. In the modern or Christian era the mind grew conscious of its spiritual nature and thereby passed beyond the classic equipoise of body and soul. The Romantic Style which now prevails has lost the flawless corporeality of Hellenic beauty and gained instead a heightened individuality and inwardness. In music the modern mind, enjoying the consciousness of its infinite freedom, feels most at home.[25]

The achievements of the idealistic philosophy of art are somewhat marred by a tendency to diminish the distance between original and analogue, i.e., to divinize artistic creation. The artist's dignity as a "genius", a seer of metaphysical truth, eclipses his terrestrial office, viz., the making of pleasing images. In a revulsion from those bold and airy constructions, later authors either reverted to the less exacting principles of classification which may be taken from the diversity of media and sense-organs, or, following Croce, they discarded the problem of a system of the arts as artificial,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Yet it is not necessary to take so radical a course. In an attempt to rehabilitate the idea of a "natural system" we may point out that the various arts are, and always have been, engaged in mutual co-operation. The pictorial arts, for instance, furnish illustrations for literature, music and poetry combine, with either of the two taking the lead, and architecture lends its help to stage-craft. Furthermore, the rules regulating this collaboration point to genetic affinities between the arts. The ease with which dancing and music, or music and poetry, unite into composite structures recalls the fact that they evolved through differentiation out of a primeval unity.[26] These observations suggest the existence of a system of essential affinities. The natural framework for the collaboration of the arts is found in the *fiesta* or celebration. Instead of erecting an abstract system of relations, we may derive them from the actual interplay of the arts as they meet on their common playground. The natural system of the arts is embodied in the "festival"—the locus of art in life. The arts are conjoined into a working community by the object of celebration, affirmed and exalted by each of them in its own language.

The basic affirmation of life is either *embodied* (drama, poetry, dancing—all requiring the human body for their performances), or *framed* (architecture), or *reflected* (painting and sculpture as the chief representative arts). The common denominator of the three modes of expression is the *voicing* of artistic praise in music which, as the medium of celebration, permeates and blends the distinct spheres of embodiment, reflection, and framing. In the normal local distribution, the arts of the first group occupy the center as the dramatic play does in a pageant or religious feast, architecture supplies the frame and shelter, sculptures and murals, placed in the middle region, reflect the central drama, while the musical sound, escaping such localization, fills the entire spatial expanse from center to periphery. The temporal mode of the arts shows a parallel diversification. The arts of embodiment, and with them music, are most intimately involved in the temporal flux. They eternalize the moment by filling it to the brim with an overpowering presence. Architecture salvages the fleeting existence by negating the flux and erecting the abiding shelter for countless reiterations. The Reflecting Arts mediate between the extremes. They endow the fluctuating now with permanence by selecting what Lessing called the "pregnant moment".[27] This scheme of the realm of arts mirrors man's relation to his world. As man is the organizing center in his environment, so are the arts of embodiment in the realm of artistic semblance; and the "peripheral" art of building corresponds to the cosmic and terrestrial setting of human existence.[28]

(III) Art is a province within the wider compass of life. The attempt to determine its sphere of competence and its relation to the principles which rule life in its entirety gave rise to two antagonistic conceptions. On the one hand, art was viewed as subserving a purpose beyond aesthetic gratification, and the aesthetic judgment was made dependent upon a moral appraisal; on the other, an absolute aesthetic autonomy was proclaimed. The classic example of the subordination of art to non-aesthetic values is found in Plato's *Republic*, where Socrates politely ushers the poets out of his Best City.[29] Ruskin condemning Renaissance art on the ground that it is morally corrupt is another case in point.[30] The opposite thesis was advanced by the exponents of the Art for Art's Sake Movement who extolled a beauty exempt from moral censure.[31] This antithesis does not deserve to be taken seriously as a genuine philosophical alternative. The notion of an absolute autonomy flies in the face of the facts. Only on pain of disrupting life can we conceive of art, or of any other activity, as an independent domain. The real problem in hand is to fit art into the unified pattern of life without violating its innate laws. Life must be so ordered that its sovereign value, the Good, accords with the exigencies of beauty instead of curtailing and bending them by an alien rule.

This is the line of thought along which philosophy from its inception tried to solve the problem. The famous catharsis theory affords a characteristic example. In order to achieve catharsis, the pleasurable purge of emotions such as pity and fear, the tragic plot, Aristotle points out, must conform to certain moral requisites. If it shows the hero as a malefactor suffering a condign punishment, it may point a useful lesson but fails to attain its artistic purpose. Nor should it outrage reason by letting the rogue triumph or the completely innocent man suffer. The good plot must wisely observe the familiar disproportion between a relatively small guilt and the magnitude of the ensuing calamity. Thus it gives a truthful image of human affliction without disclosing the rationale of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

man's suffering and rivalling with philosophical theodicy. But the pity which it arouses in us is accorded to one worthy of it, and our fear well founded: *nostra res agitur.*[33]

In a kindred fashion, the play theory confers upon art a high moral significance while safeguarding it against moral servitude. This theory, the classic answer to the query concerning the place of art in life, goes back to Plato.[33] Friedrich Schiller renewed it in a modified form;[34] and modern sociologists and psychologists, following Herbert Spencer's example, re-interpreted it in the spirit of evolutionism.[35]

Play, an active pause in the serious business of life, imitates life. As its illusory duplication it is, on the one hand, inferior to life itself, "mere" play. On the other hand, its sublime playfulness is the likeness and anticipation of the most serious of all human occupations: of worship and intellectual contemplation. By releasing us from the petty cares of our workaday existence, it verges on august seriousness. Its place is in the forecourt of the adytum, both pointing forward to the sanctuary and causing us to linger. It is related to the supreme intellectual fruition as, for example, the Oberammergau Pageant is to the Mass. Both are concerned with the mystery of salvation through the incarnate Word—the pageant representing it as a play, the Mass enacting the mystery itself.

In Plato's ideal state, the imitative play (*paidiá*) is a form of education (*paideía*). Through it the mind which is not, or not yet, capable of grasping rational perfection itself becomes conformed to its image by receiving the imprint of rhythm and harmony.[36] In the same vein, Schiller conceived of the gratification of the artistic play-impulse as a high indifference and preparedness, the intermediate stage in the development of man from a sensuous into a rational being.[37] However, an ambiguity lurks in the notion of art as a playful occupation with images. The charm of the image may free us and lead us on the vision of the supersensible original. But it also may enthrall us by the subtlest of all sensuous pleasures. "All great things are perilous"[38]—and so is art. The view which allots to art the rank of an educator is, at the same time, an instrument of unrelenting criticism. But this criticism, if rightly understood, is not a moralizing censorship which fetters art with puny scruples. It rather gives voice to an urge indigenous to artistic creativity—to the "artistic conscience"—which is disdainful of facile charm and will not let us stoop to the "pandering Muse". The harsh treatment meted out by Plato the "host of imitators" is ultimately an insistence on greatness in art.

The play theory unites the manifold trends of the philosophy of art into a single focus. It completes the conception of art as a making of imitative images; it reveals the profound agreement between this conception, the matrix of all philosophy of art, on the one hand, and the modern speculative notion of creative imagination on the other; and it finally links the theory of artistic production with that of a natural system of the arts by discovering in the festival the orderly co-operation of the arts. *Art is a form of celebration.* In this formula, "celebration" signifies a type of play; and the specific difference, marking off art from other forms of celebration, is "creation of images". *Art celebrates through imaginative creation.* In Ruskin's words, it is "praise of something that we love".[39]

**phonautograph.** See phonograph.

**phonograph.** An early dream of the human mind was the artificial reproduction of sounds, perhaps because the fleeting and impalpable nature of sound made such a feat seem doubly marvelous, so remarkable indeed as to take on the character of magic. We need to accept the earliest tales with great reserve since from the speaking heads of the column of Memnon to the talking dwarf of Roger Bacon and the talking head of Athanasius Kircher they seem to have depended on trickery. The voice of a hidden operator, transmitted through a speaking tube and resonated so as to seem mysterious in quality, seemed to issue from the lips of the image. These devices, as well as the pathetic attempts of Porta to preserve sounds in a closed lead cylinder, belong to the pre-history of phonographic devices. They are interesting only in showing the fascination that the idea held for the human mind long before the nature of sound was sufficiently well understood to permit the problem to be attacked with a reasonable prospect of success. The first steps which were to lead to the phonograph were taken by Leon Scott in the mid-19th cent. When the operator spoke into the horn of his **phonautograph,** the sound waves produced moved a parchment diaphragm back and forth. To the lower side of this diaphragm a bristle was attached. As the operator spoke into the horn, he simultaneously turned a cylinder covered with smoked paper by means of a crank. On this paper the bristle traced a sinuous wave pattern. This apparatus strikingly anticipated the Edison phonograph in its salient features, but it could not play back. It could only record the wave pattern of sounds spoken into its horn.

Even more amazing is the description by Charles Cros dated 1877 which envisaged the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

reproduction as well as the tracing of a wave pattern of sounds. His proposed apparatus made a tracing of the vibrations of a membrane and utilized the tracing to reproduce the same wave pattern as sound again. The tracing was to be made on a disc covered smoothly with wax. Although Cros himself called the apparatus the **parlerphone**, an article by the Abbé Lenoir used the finally accepted term *phonograph*. Not the least remarkable feature of this description is the fact that it antedates by two weeks and two days the invention of Edison.

The Edison apparatus used a stylus of steel which incised an intermittent pattern on a revolving cylinder covered with tinfoil. Edison did not develop the machine further, and his apparatus was elaborated by other workers including Bell. The stylus was modified so that it made a continuous tracing on a wax cylinder. Early models rotated the cylinder by means of a battery-operated electric motor. This was replaced in the commercial type by a clock-work motor. This machine had considerable success, although reproduction was imperfect by modern standards. The wax cylinders were fragile and it was some time before the problem of producing them in quantity was solved. At first numerous repetitions by the performing artist were necessary, and truly for such work the performer needed superlative powers of endurance. Finally, the original record was reproduced in reverse by depositing a shell of copper on it, thus producing a mould or matrix which could be used to produce a large number of reproductions.

The modern record in the form of a disc appeared in an apparatus devised by a German-American called Berliner. In these discs a core of metal was covered with a recording surface of wax. So far recordings had been made by mechanical means. An apparatus described to the French Academy by François Dussaud, the **microphongraph Dussaud**, incorporated a microphone and a telephone mouthpiece activated by a battery.

As the radio in more recent times gained a large audience, the phonograph lost popularity because of this increasingly formidable competitor, and the industry underwent a crisis. By this time, it is true, recordings had been made of music by many famous operatic and concert artists. Ethnologists had grasped the significance of the machine for the study of exotic and folk music. Little symphonic music had been recorded and most of this was available only in versions with cuts. In striving to attract a larger public very complete series of symphonic recordings were made, complete operas were recorded, as well as much chamber music. Special interests were fostered by "Society" issues which concentrated on one field, such as the works of Purcell or of Delius.

Not only were recordings made electrically, but the amplifying stage of the radio with its loudspeaker was adapted to the phonograph. The phonograph became a piece of furniture rather than a machine which sometimes suggested the laboratory of the alchemist. The horn was incorporated in the cabinet. The magnetic pick-up replaced the old sound box. The result was an apparatus which in power, fidelity, and purity was an incomparable advance. Nevertheless, perhaps nothing so attests the adaptability of human tastes and of the human ear as the fact that early phonograph records were so widely regarded as musically acceptable.

Finally, highly perfected phonographs developed for broadcasting have exerted a powerful influence on public taste by broadcasting recorded music, thus multiplying a thousand-fold the reach of a fine performance but at the same time contributing to the technological unemployment of the performing musician. Stations from the earliest experimental stages of broadcasting employed records for broadcasting purposes, and their use as cheap fillers for a program is by no means a thing of the past. Nevertheless, the daily broadcasting of symphonic records by such stations as WQXR must be considered a major force in the democratization of music.

—C.W.H.

**Phonophotography.** The science and art of recording and analyzing sounds for the purpose of measurement and adequate description.

"Let me describe a typical procedure in recording the performance of a singer or player, speaking in terms of the singing situation. The singer comes into the acoustically treated and musically acceptable studio laboratory. The set-up looks very much like a radio studio. The singer is alone in the room, standing before a microphone, without any surrounding disturbances, and aware of the fact that his voice is going to reach a large and critical audience. The song may be one of his first choices for artistic rendition. He sings in his best artistic mood, as it were, to the large audience over the radio. Thus he should feel that he has a large and inspiring audience not only at the time of recording but through

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

a phonograph record and all the objective facts revealed by the camera.

"In the adjoining room, there is equipment for the recording by phonograph and camera, several of which may record simultaneously. Thus a permanent phonograph record is made and a battery of cameras simultaneously records pitch, loudness, time, and timbre for every note on moving picture films in terms of frequency, amplitude, duration and wave form. These films contain the complete and highly detailed permanent records of every significant element in the musical sounds; namely, the tonal, the dynamic, the temporal, and the qualitative which become the research material for measurement, reconstruction, and interpretation. From the data in the film, a performance score (q.v.) is constructed.

"The studio is of a character that musicians and listeners are accustomed to. The record contains not only the singer's voice—pure and simple, but is modified by various acoustic characteristics of the room and possibly from outside sources. To eliminate such room and environmental characteristics from the recorded voice, the singer may repeat as nearly as possible the same rendition in an adjoining dead room. A dead room, for this purpose, is one which has been built and treated accoustically so as to eliminate practically all reverberation from the walls, ceiling and floor of the room and any of its necessary contents. It is also proofed against sounds from outside. By repeating the original rendition in this room we have the record of the sound of the voice in a so-called musical environment for comparison with the sound of the voice by itself in the dead room.

"In all these recording devices, the human element from the experimenter must be eliminated so that all the recording is done automatically with far higher precision than could be produced through the control by eye, ear, or hand. The sound wave must speak for itself so that it can be faithfully interpreted whether it represents varieties of sound in nature or in art, regardless of how generated —through voice or instrument." C. E. Seashore, *Pioneering in Psychology*: University of Iowa Press, 1942. See University of Iowa Studies in Psychology of Music, Vols. I, III, and IV.

PHOTOGRAPHY. Generally photography is considered only as an auxiliary technical means for recording. Being mechanical it "cannot" produce art. On the other hand, if any interpretation tried to elevate photography to art, it was influenced by the aesthetic-philosophic concepts that circumscribed painting. So photography with "art" ambitions has remained in rather rigid dependence on the traditional forms of naturalistic painting; and like painting it has passed through the successive stages of all the various art "isms" though in no sense to its advantage.

Fundamentally new discoveries cannot for long be confined to the mentality and practice of bygone periods. When that happens all productive activity is arrested. This was plainly evinced in the photography of the last hundred years, which has yielded little results except in those fields where, as in scientific work, police records and reporting, it has been employed without art ambitions, but with real knowledge of the science and technology, physical optics and chemistry of photography. Here alone did it prove the pioneer of an original development, of one peculiar to itself.

*Art or not?* In this connection it cannot be too plainly stated that it is quite unimportant whether photography produces "art" or not. Its own basic laws, not the opinions of the art critics, will provide the valid measure of its future worth. It is sufficiently unprecedented that such a "mechanical" thing as photography, and one regarded so contemptuously in an artistic and creative sense, should have acquired the power it has, and become one of the primary objective visual forms, in barely a century of evolution. Formerly the painter impressed his outlook on his age. We have only to recall the manner in which we used to look at landscapes, and compare it with the way we perceive them now—"photographically". In analyzing photography we find that this means the incisive sharpness of the camera portraits of our contemporaries, pitted by pores and furrowed by lines; the air-view of a ship at sea moving through waves that seem frozen in light; the enlargement of a woven tissue; the chiselled delicacy of an ordinary sawn block of wood; in fact, any of the whole gamut of splendid details of structure, texture and surface treatment of whatever objects we care to choose. These examples are typical of the way in which photography records the visible world.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

*The new experience of space.* Through photography, and in even greater measure through the motion picture, we can participate in new experiences of space. With their help, we have attained an enrichment and sublimation of our appreciation of space, the comprehension of a new spatial culture. Thanks to the photographer, we have acquired the power of perceiving our surroundings with new eyes.

*A genuine medium.* But all these are isolated characteristics, separate achievements, not algether dissimilar to those of naturalistic painting. In photography we must learn to seek, not the "picture", not the aesthetics of painting, but the ideal instrument of expression with the entirely new medium: light sensitive emulsion, the self-sufficient vehicle for creative work.

*What is photography?* Through the development of black-and-white photography, light and shadow were for the first time in their interdependence fully revealed. Through the development of reliable artificial illumination (more practically electricity), and the power of regulating it, an increasing adoption of flowing light and richly graduated shadows ensued. Through these a greater animation of surfaces, and a more delicate optical intensification was possible. This multitude of gradations is one of the fundamental "materials" of photography, a fact which holds equally good if we pass beyond the immediate sphere of black-white-gray values and learn to think and work in terms of color. When pure color is placed against pure color, flat, plain tone against tone, a hard, decorative, poşter-like effect generally results. It is necessary to state here that non-objective painting tried to overcome exactly this deficiency, and this effort is one important part of its "problem area".

A classical device to dispel the poster-like effect, and create a more delicate and melting impression is to use colors in conjunction with their intermediate tones. Through the black-white-gray reproduction of all colored appearances, photography has enabled us to recognize the most subtle differentiations in both the gray and chromatic scales: differentiations that represent a new and hitherto unobtainable quality in visual expression. That, is of course, only one point among many. But it is the point where we must begin to master photography's genuine properties. The point where we start to deal more with the artistic function of expression than with the reproductive function of portrayal.

*How to start to teach it.* In teaching photography, one could start with portrait, still life, or landscape. But, looking at a face, e.g., one will discover how complex is the task of photographing it. To observe the multiplicity of details, the resemblance of the person, his psychological expression, the texture of his skin, the subtle relationships of the dark and light and middle values of the face, the aspects which reveal its most characteristic expression, etc. is a complicated task. How can one hope that a beginner who has never done any work in photography will be able to master all these complexities at once. Therefore the problem is to approach photography from an angle which directs attention to the fundamentals.

*Photography without camera: the Photogram.* The basic element of photography is the light sensitive emulsion. Exposed to light this will record the varied intensity of light sources in black and white and gray values. The student may start his experiments by utilizing this principle, without the use of any camera. The technique of the photogram is based on this preceding principle. The photogram is as old as photography itself. Fox Talbot made the first crude photogram in 1835 by laying lace on the photopaper he invented. It was re-invented in the 1920's by Man Ray and L. Moholy-Nagy.

Exploiting the unique characteristics of the photographic process—the ability to record with delicate fidelity a great range of tonal values—the photogram provides the path to basic discoveries with the interplay of light. The Photogram is the key to understanding the photographer's medium. As the painter uses color, and the composer uses tone, the photographer "paints" with light.

An almost endless range of gradations is one of the fundamental properties of photographic expression. These subtle differences are achieved most easily in this cameraless work—the photogram.

A good photogram has an infinite refinement of flowing gray values between the black and white poles. Their optional use, organized through the will of its maker, creates photographic quality.

The photogram conjures up as many interpretations as it has viewers and with new discoveries the original range of these elements can be enlarged upon. For example, a new method of recording light values may occur when material is put under mechanical stress as in painting on glass and pressing a

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

second glass plate down upon it while the paint is still wet and ductile, flattening out the painted lines to a degree which vary with the pressure applied. This glass plate can be then used as a negative in an enlarging apparatus, as George Kepes experimented, producing photographic records of the effects of the stresses. By substituting photographic evidence for guess-work in computing the performance of materials, this method may become an important contribution to industrial progress similarly as M. Heteny's experiments with photo-elasticity developed for purely scientific reasons. The method of three-dimensional photo-elasticity is based on the experimental fact that samples of phenolic resins, such as Bakelite, Marblette and Trolon, when annealed in a loaded condition show a complete preservation of (a) the elastic deformation and (b) the accompanying bi-refringence produced by the loading of the annealing temperature as it is described in the article, "The Fundamentals of Three-Dimensional Photoelasticity" by M. Hetenyi [Research Laboratories, Westinghouse Electric & Mfg. Co.]. A similar method is used for checking the hardening of eye glasses used in industry for accident prevention. Seeing such a glass behind polaroid, through the appearance of a Maltese cross—an immediate decision can be made as to its perfect execution as the cross indicates diagrammatically equalized centered stress performance. Of course, his experiments may be used one day as elements of artistic creation.

Both types of **light records**, in black and white and in color lead to a new grasp of spatial relationships and spatial rendering. The receding and advancing values of the gradations, which are nothing but projections of the **light tracks**, can be used for space articulation. This new approach leads to the understanding of new art forms, especially architecture and the motion picture, both of which operate with light. It simultaneously gives an insight into the idea of space-time. This work does not have to be essenially for the sophisticated. Both the photographic amateur and the layman, acquiring through the photogram a deeper understanding of light and space values, will be stimulated to exploration, and afterwards to a fuller use of all the potentialities of the camera.

*The lesson for camera work.* The photogram teaches that the same characteristics of gradation and contrast have to be applied to the camera work too. Good photography with the camera allows us to capture the patterned interplay of light and shadow in the same way as in cameraless photography.

*Light modulator.* This is shown especially well with the help of a light modulator. A light modulator is a simple device; its function is to catch and reflect, to modulate the light. Any object may be considered a light modulator, as it reflects the light, and the colors of the spectrum differently, depending upon its substance and the different way its surfaces are turned toward the light source. As the rays strike the object it reflects some rays, absorbs others; permits others to pass through if it is transparent, while refracting them to some degree. If the substance is translucent, it diffuses the rays that are neither reflected nor absorbed. The human face is the best-known of all light modulators, and it ranks near the top of the list in complexity. A face contains few straight lines; flat surfaces, if any, are small. Surfaces and lines are nearly all curved and the surfaces have mostly compound curvature—curving in many directions. Surface, texture and color vary with the person's age; the skin of a baby is vastly different from that of a patriarch, and there are countless degrees of differences between. Then there are the eyes, which present, in addition to their general expression of personality, specific light-modulating problems of surface, texture, shape and substance. The beard, mustache, present fine problems in light modulation; similarly the hair, the eyebrows, and the eyelashes. Finally, there are the lips and the teeth, and the ears—rich studies in light and shadow.

*Simplified versions.* With all the complexity of substance, surfaces, contour, color and texture, the face is a marvelous subject for study of the modulation of light. In practice, however, as already mentioned, it is a rather difficult task. It is better if the student manufacturers simple light modulators out of paper, metal sheets, plastics, or other materials which can be bent, molded or cut to produce various surfaces to modulate light, in the photographing of which he must become proficient.

Few detailed directions are necessary for the actual making of the light modulators. Each is the product of the individual's own ingenuity, dexterity and interest. The variety of modulators is endless, with various bends, cuts and folds of the paper. Adding other factors to this—another type of material, more shiny and oqaque, or more transparent; metal and glass—all these will change the modulating qualities, creating more depth and illusions of space. Photographing the modu-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

lator means to try to define it by lighting This can be accomplished from one or various angles, or with different combinations of light, to strive to reveal it to its best advantage. The photographer's task is to identify unmistakably the true shape and nature of his object, in this case the modulator, for the spectator. With some thought and practice one will be able to apply this information to any subject matter one wishes to photograph.

*Creative Approach.* After learning how to photograph a series of light modulators made from paper, metal, glass, the student must try to shoot more complicated objects, which include all the properties and problems of the whole series of light modulators. Having studied each problem separately, he will know what each type of modulation will mean in the finished photograph.

There is an important application of the light modulator in the field of creative photography. Its effects produce emotional reactions through the combinations of shape, contour, texture, color and lighting. Thus we may paint with light as surely as we can do this by painting with oil and pigment. This is the new frontier of photography.

Surfaces, textures, and structures can be understood as light modulators; so also macro and microscopic photographs and solarization. After such experiences there will be no difficulty in photographing any portrait, landscape or industrial scene in any required way.

There will be many shapes and types of surfaces, definite space relationships, depth, height, comparative dimensions; inter-penetrating objects; surfaces that meet and cut one another; transparencies, mirrorings, etc. Controlling the uses and effects of each individually and in relation to one another in a picture, one will be able to apply them as elements of a broad photographic concept allowing one to move surely, swiftly and efficiently about one's work.

*Sublimated Technique.* In photographic rendering—considered as the objective fixation of the semblance of an object—one may find just as radical advances compared with the prevailing naturalistic paintings, as in direct records of light forms produced by photograms. Such particular developments of naturalistic photography are known as the bird's, frog's and fish's eye views, partial mirrorings, reflections, penetrations, superimpositions, etc. Their systematic co-ordination opens up a new field of visual presentation in which still further progress becomes possible. It means an immense extension of visual possibilities. Photography can render speed or stop speed or register precisely objects in a hundredth, thousandth, or a millionth of a second. It can "see" through mist, even in the dark by using infra-red emulsion. It can penetrate and record the inside of opaque, solid objects with x-ray photography. Indeed, this advance in technique almost amounts to a psychological transformation of our vision, since the sharpness of the lens and its unerring accuracy have now trained our powers of observation up to a standard of visual perception which embraces ultra-rapid snapshots and million-fold magnification of dimensions employed in microscopic photography.

It is obvious that photography imparts a heightened and increased power of sight in terms of time and space. This process is only at its beginning. A plain matter-of-fact enumeration of the specific photographic materials in a purely technical sense enables the student to divine the power latent in these elements.

*The eight varieties of photographic vision.* (1) **Abstract seeing** by means of direct records of forms produced by light; the photogram which captures the most delicate gradations of light values, both chiaroscuro and colored. (2) **Exact seeing** by means of the normal fixation of the appearance of things: reportage. (3) **Rapid seeing** by means of the fixation of movements in the shortest possible time; snapshots; stroboscopic photography. (4) **Slow seeing** by means of the fixation of movements spread over a period of time: i.e., the luminous tracks made by the headlights of motor-cars passing along a road at night: prolonged time exposures. (5) **Intensified seeing** by means of: [a] microphotography; [b] filter-photography, which, by variation of the chemical composition of the sensitized surface, permits photographic potentialities to be augmented in various ways —ranging from the revelation of far-distant landscapes veiled in haze or fog to exposures in complete darkness: infra-red photography. (6) **Penetrative seeing** by means of x-rays: radiography. (7) **Simultaneous seeing** by means of transparent superimposition: the future process of automatic photomontage. (8) **Distorted seeing:** optical jokes that can be automatically produced by [a] exposure through a lens fitted with prisms, and the device of reflecting mirrors; or the dictograph; [b] Mechanical and chemical manipulation of the negative after exposure.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

*Series, image sequences.* There is no more surprising, yet, in its naturalness and organic sequence, simpler form, than the photographic series. This is the logical culmination of photography. The series is no longer a "picture", and none of the canons of pictorial aesthetics can be applied to it. Here the separate picture loses its identity as such and becomes a detail of assembly, an essential structural element of the whole which is the thing itself. In this sequence of separate but inseparable parts a photographic series inspired by a definite purpose, can be either a potent weapon or tender poesy. The prerequisite for this is the realization that a knowledge of photography is just as important as that of the alphabet. The illiterate of the future will be ignorant of the use of the camera and the pen alike.

*Photogenic vs. Photocreative.* Peculiarly photography, which originally had been created for exact recording of the immediate reality, can become the tool of the fantastic, dreamy, super-real, and imaginary. The ardent desire to penetrate the subconscious and to reach a more governable mechanism of inspiration is most probably an eternal human component. Cameraless photography, super-imposition, prisms, photomontage, mechanical or chemical distortion, the use of negatives and solarization—are all legitimate photographic means of recording. At the same time they help to create a more complex language of photography.

Signs indicate that, with a changing intellectual attitude, the photographer of today is no longer exclusively interested in photogenic renderings, but more in situations synthetically produced. Objects, situations, persons are called **photogenic** if they have the properties of producing good photographs. These properties can be of most diverse nature: roundness, richness in texture, transparency, mirroring surface, skeleton structure, etc. His attention is focused on the control of photographic effects, rather than on the event itself. He tries to acquire not only a photogenic but a photocreative mind. He will not only select what he finds, but he will *produce* situations which for him contain the necessary qualities for photographic expression with devices so far unused and neglected.

Such a development seems to be in tune with the historic development of artistic expression. A growing control over the means usually liberates creative energies which now can be concentrated directly on the problems to be expressed. These problems are usually of a subconscious nature, determined by unconscious motivations behind which emotional forces stand. These emotional forces can be expressed by automatic actions in any medium.

*Automatism.* It is obvious that the more easily someone handles his medium, the easier his automatic recording in this medium will be. Automatic writings are used today as inspiration and source material for surrealist poetry. **Automatic writings** were originally psychological experiments. They were produced in a kind of self-hypnosis, writing down thoughts occurring without conscious control.

It is unimportant where the inspiration to express emotional forces comes from, whether from scientific, technological or any other layers. The main task remains that the artist must have the ability to produce artistic coherence of the means he uses. In this way photography which was formerly the technical rendering par excellence, can be used for subconscious recordings.

*Realism in photography.* The paradox is that our mental habit structure has been built up in the 19th cent. with exact observation and recording of the immediate reality. The problem of the subconscious had been insignificant in the 19th cent. Fantasy and emotional longing was substituted then by telescopic and microscopic miracles, x-ray and infra-red penetrations. These phenomena, motion and speed, electricity and wireless gave food enough to the imagination without introducing subconscious automatism. Even the introverts turned away from their possible psychic problems toward the more external events. Photography was the easy key, opening the doors to the miracles of this external universe, within the reach of everyone. But even the most astonishing records were *objective* representations though they went in some cases beyond the observation capacity of our eyes as in the already mentioned high speed, micro, macro, x-ray, infra-red and similar types of photography. This was the period of "naturalism" or "realism" in photography.

*New directions.* The new arts opposed the flattening simplicity of such a "perfect" explanation of reality, a reality based upon sensorial experience and logical derivation only, without the acknowledgment of the realm of the subconscious. The expressive character of the automatic writings, as employed by surrealist authors, with their strong, direct vision, with the new and fertile bonds between worn out words, through misspelling

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

and recoining of idiomatic expressions, gives an analogy for a new use of the photographic means. Indeed, photographers of different countries try to enlarge the expressive content of photography by fusing the customary with the unexpected.

Photography is the translation of a light-saturated world into black and white and gray gradations. This is the basic departure of the photogram. The photogram changes the habitual way of viewing the world in its relative black and white values to its complete reversal; black becomes white and white becomes black. (Similarly **solarization** is the surprising change from positive into negative). This is not, however, the only performance of the photogram. By reversal of the values a new world arises out of the hidden: a supernatural glow with sublime magnificence—a play of mysterious light sources with radiating aura enveloping the objects, giving them fresh potentialities for new relations. This also applies to superimposition.

*Superimposition.* The mechanical process of printing photos over each other opens new territories for imagination and emotional experiences in simple or sophisticated manifestations. Superimposition is the best of all visual means to record a dream. It overcomes space and time fixations, it is able to unite strange and diverging subjects into new entities. Superimposition is the transfiguration of the insignificant singularities into meaningful complexities; banalities into vivid illumination. The transparent quality of the superimpositions often suggest transparency of the content as well, revealing unnoticed structural qualities of the objects used.

*Photomontage.* Another way of extending the means of photography—besides straight camera work—is the photomontage. It goes back to the cubist colleges but it has developed its own technique leading to a kind of witches' sabbath. The results may be weaker or stronger depending upon the temperament of the **photomonteur.** Photomontage was known to the old photographers as well, who were sometimes bound to assemble individual photographs into group pictures. In this type of patch-work-photomontage the intention was to present to the spectator a normal camera record.

Around 1920 the Dadaists (the predecessors of the Surrealists) enlarged upon the meaning of such photomontage. Their mosaics, made up of many cut-out details showed clearly single elements crudely glued together. This was a conscious part of their policy to annoy the public, demonstrating with a "childish" technique that they "didn't care" for artistic standards. But there was something more behind that. The Dadaists exhibited brutally the torn and divided photographs, the rough cut of the scissors because they had a contempt for any kind of illusion and because they wanted to produce with these means a "counter war", an emotional pandemonium with the atmosphere of fury and ridicule directed against World War I.

Artistically these photomontages are reminiscent of the first futuristic, bruitisic symphonies which combined noise and hubbub to a thundering orchestration. The photomontage came later to a more "rationally" organized form looking more graspable though with the penetration and fusion of relationships which are normally not recognized. Photomontage also attempted to formulate simultaneous presentation of events. Photomontage developed toward the recording of problems occurring on the threshold between dream and consciousness; a tumultuous collision of fantastic details from which hidden meaning flashes: the idea of visual poetry with its bitter jests, sometimes blasphemy.

Photomontage often shows the vicious side of the creature; often the plot against the insufficient; funny and witty; tragic and earnest. Most photomontages demand a concentrated gymnastic of the eye and the brain so that the speed of visual digestion and associations might grow immensely.

*Color photography.* One would think that color photography offers ideal means for "light creation", because colored light can be recorded today mechanically with the utmost delicacy. However, as long as we devote our efforts in color photography to the repetition of classical problems in naturalistic representation we cannot hope for creative results. Most of the problems of color photography even if they seem unusual and complicated, have been solved by the painters of the past. Color photography passes through the same stages as easel painting because of the ease of its application. Most people are quite unaware of the magnificence of old paintings, and happily consider their own discoveries as original. But color photography can only be developed by someone who understands its unique characteristics, its independent original "quality". With our present knowledge of processes we are already able to specify a number of indigenous properties of color photography and hope that a fuller knowledge will be developed as the work progresses.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Among significant properties of the color emulsion and of the photo apparatus, there is the ability to reproduce mechanically light and shadow in color, such as Goethe's complementary shadow effects, which cannot be observed exactly enough by the eye, or which cannot be represented with the same speed, exactness, and true quality by the easel painter.

There is the possibility, too, to record color values, not to create the illusion of a naturalistic scene, but to give spatial values to different colored light areas within a colored light display. There are experiments with color filters, motion diagrams of actions as moving with the camera towards colored light phenomena and—of supreme promise—color photograms.

*Impressionism.* It has always been one of the aims of painting to reproduce manifestations of color with the same intensity with which they appear in nature. This is nothing new to connoisseurs of impressionist painting, but few are aware that in many points the development of Impressionism has contributed to the problems of photography. Seurat and the other pointillists even anticipated the *additive* method of color photography. He set points of red and green adjacent to one another so as to produce, at a sufficient distance, the illusion of a broad field of yellow, just as in the autochromatic Lumiére photographic plate or the Dufaycolor film. The Impressionists not only created a new feeling for color but also laid the foundations of a new security in the treatment of "space". The Impressionists dared to take the first step toward objectivity in optical problems. They were the first to suppress the narrative, story-telling element in painting in favor of color.

*Cézanne's problem.* Cézanne's artistic development most probably will for a long time to come remain the practical foundation of color photography and the color motion picture. Cézanne produced the colored phenomena of light playing on the surface of things; that is, he tried to render the most intense color effect that light in nature can produce. In order to reproduce these effects in paint, the Impressionists invented an extensive scale of new technical artifices, and Cézanne developed these techniques still further. Observed close at hand, most of his pictures consist of opalescent single strokes, points, tracks of color (basically similar to Seurat's method), only more conscious of their receding and advancing spatial values. These color spots, seen at a proper distance, resolve into a colorful unity, glowing with light. This analytical, dissective technique permitted the representation of nature and space with an intensity hitherto unknown. Once this step had been taken, Cézanne could direct his interest to the objective problems of a painter who speaks through color, namely, to the relation of colors to each other. In his late pictures he uses nature as a point of departure but he quickly overcomes the subject matter and uses it merely as a framework for the composition of color areas and space-composing color tensions.

*Abstract painting.* Painting continued to develop. In the 20th cent., by way of expressionism and cubism Cézanne's work had opened up a path to abstract painting. The abstract painters seized upon color as the direct medium of subconscious recordings with an intensified expression. But it has not yet been possible to create with pigments the highest intensity of color, as seen in nature through reflection or absorption of light by various bodies. Thus once more the same ancient problem of colored light rendering comes up; but no longer on a naturalistic plane. For a solution the painter has now the proper element, direct light itself, movable and multi-colored. This light can become active, not only through the differentiation of reflection, or through the power of absorption of any particular material upon which its rays are cast, but in the first instance through the vitalizing, planned action of the artist who uses it to create. It is here that the real conquest of color begins: through the efforts of the artist who is informed about the historic body of attempts to create with color, with colored light. The true *kinetic* representation of color values will bring the first great sensation of direct light creation. Through a new form of **montage** by purely optical means and not by sentimental content will continuity and composition be established. Naturally, much time will elapse before color photography and the motion picture will reach the point where color will be divorced from the former naturalistic-illusionistic meaning.

The creation of colored shapes through light, free from such content, will probably lead to the **abstract cinematograph**, the kinetic equivalent of the static color photogram, exposed without a camera. —L.M-N.

**photomacrographs.** Direct enlargements of paintings or objects. They are enlargements of things visible to the naked eye as distinguished from photomicrographs which are

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

enlargements of objects invisible to the naked eye. Photomacrographs made with a camera and enlarging lens are free of the grain seen in projected enlargements. Photomicrographs are photographed through a microscope. See FORGERIES IN PAINTINGS. —H.M.

**photomontage.** See PHOTOGRAPHY; collage.

**photomonteur.** See PHOTOGRAPHY.

**photoxylography.** Process in which a design is photographed on wood for the wood engraver.

**phrase.** *Mus.* Metrical unit comprising as many elements as, figuratively speaking, can be stated in one breath; i.e., can be considered being generated by one initial impulse inasmuch as they are grouped around one dominating accent. A phrase may be self-sustained, or may require another phrase for balance. Phrases may be clearly separated from each other, or overlapping, when a new impulse comes into action before the first one is exhausted. The relative metrical values of phrases are emphasized particularly by the cadences at the close of phrases. The sum total of phrase relationships in a composition is the articulation of the form of that composition. See articulation; accent; form; meter. —E.K.

**phrase accent.** See accent.

**phrase construction.** See articulation.

**Phrygian mode.** See scales and modes; idiom A(2).

**phrygium.** See tiara, papal.

**phylomorphic.** A detail resembling a leaf.

**Physiologus.** Illustrated compilation on zoology put together probably in the 3d cent. A.D. in Alexandria and supplied later with Christian moralizations. The title is due to the belief that Aristotle, the greatest physiologist-natural scientist among the ancients, was the author of the book. The source of all medieval bestiaries (q.v.). —R.B.

**phytograph.** A nature print.

**pi** (Ch.). (1) Jade disc with circular perforation in the center; it is the symbol of heaven, and is used ritually; (2) brush; (3) brush-stroke.

**piano.** See MUSICAL INSTRUMENTS; mechanical instruments; NOTATION.

**piano camera.** A camera which records photographically in minute detail the exact nature of piano performance so that it may be converted into a piano performance score.

The Iowa piano camera designed by Seashore and Tiffin "is comparatively simple and highly reliable. It operates on an ordinary piano in a sound-conditioned room where the pianist can perform under very much the same conditions as in radio broadcasting. He sees or hears nothing of the recording process; but by the time he has completed the movement of a sonata, for example, hundreds of feet of film contain an exact account of every item in the performance. The camera records the time for every element in the performance in hundredths of a second, the intensity in terms of the force delivered to the string by the hammer (which can be reduced to decibels of loudness), and the use of pedals. Each note in the succession of chords has an individual record. The record as a whole is a mine of information which can be dug out in proportion to the time, patience, and insight of the experimenter.

"Here is an example of a fundamental tool, really an automatic recording apparatus, which takes the analysis of piano performance from the field of hearing and makes the performance score objective in terms of black and white where we can measure, count, and classify in strictly scientific terms. By such means we can verify or disprove the theories of the past and discover new ones. Thus, this technique is entering upon a new stage. It gives us a new type of performance score which paves the way for an original scientific approach to the analysis of principles of piano performance.

"On the basis of this type of exact information a new type of stencil can be cut on the roll for the mechanical piano player, reproducing with extraordinary fidelity the actual interpretation given by an individual artist. In comparison with this change, the ordinary player piano roll is very crude and imperfect. The task is an endless one; but like the discovery of a new continent, it leads to wealth untold.

"Strange to say, so far as I know, this is the first and only piano camera that gives a comprehensive record of the entire performance. It opens up a new frontier in the science of musical art which will be a fascinating tramping ground for the musicologist. Let me repeat, it reveals the exact interpretation given by the pianist and by transferring this to the roll of the player piano, the me-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

chanical player can do justice to the artist through the fidelity of the reproduction. Page the promoters of player pianos!" C. E. Seashore *Pioneering in Psychology,* University of Iowa Press, 1942. See Seashore, *Psychology of Music,* 1938.

**pianoforte.** See MUSICAL INSTRUMENTS.

**piano quartet, quintet, trio.** See chamber music.

**piao** (Ch.). Labels. Usually narrow strips of paper pasted to the outside of paintings on which may be written the dynasty, the artist's name and the title of the painting. —J.A.M.

**piao pei** (Ch.). The mount of a picture. Generally a brocaded area around the picture spaced and applied somewhat formally.

**piccolo.** See MUSICAL INSTRUMENTS.

**picking.** *Textiles.* Placing lines of weft between the divided warp threads.

**pictograph.** Pictography may be defined as that form of thought-writing which seeks to convey ideas by means of picture-signs or marks more or less suggestive or imitative of the object or idea in mind. —J.M.M.

**pictorial.** See ex libris.

**pictorial elements.** See PAINTING; painterly.

**pictorial relief.** See relief.

**pictorial representation.** The art of rendering the shape and character of objects with a graphic art medium.

**picture dealer.** See FORGERIES IN PAINTING.

**picture line.** See PERSPECTIVE.

**picture motet.** See music printing and engraving.

**picture plane.** See PERSPECTIVE.

**picturesque village.** See folly.

**pier** (L. *petra,* rock). (1) A plain detached mass, as of masonry, usually serving as a support. (2) A solid portion of a wall between window-openings, etc. (3) In archeological excavation: A detached mass, as of earth, preserver or retained for study of the strata. —J.M.M.

**pieta.** Devotional image derived from imagery in religious poetry and representing St. Mary mourning over the dead body of Christ in her lap. The motive was first introduced into art in Germany shortly before 1300 and spread from there to other parts of Europe. —R.B.

**pietra dura** (It.) Stones used for inlay; hence hard and valuable stones.

**pigment.** Although this word can be used for any kind of coloring matter, in the arts it is chiefly applied to a granular material taken up as a power and ground into a medium to form paint. Pigments have furnished subjects for the writing of numerous treatises since ancient times. The number of such coloring materials is large, hundreds of items being now listed by dealers who sell them. In the technology of paints it is common to classify pigments according to their color, although they are sometimes arranged according to their origin, natural or artificial, and sometimes according to their chemical composition. See COLOR; dye. —G.L.S.

**pig-skin.** *Book.* The skin of the pig used in binding, can usually be distinguished by the innumerable small hair holes close together but readily imitated.

**pi hua** (Ch.). (1) Wall painting, fresco; (2) brush stroke.

**pilaster.** A rectangular feature in the shape of a pillar attached to a wall from which it projects. It generally consists of a base, shaft, and capital. —J.M.M.

**pile.** (1) The substance of the rug projecting beyond the level of the warp and weft; the threads projecting from the knots tied around the warp strings; the body substance of the rug. Pile weaving may have been suggested by grass and shrub growth and fur of animal skins. Early Egyptian pile weaving of line was deficient in density and softness and failed to cover the foundation texture. (2) See HERALDRY. —B.E.J.

**pile carpet.** See carpet structures.

**pillar.** A firm, upright, separate support; column, pier.

**pillar print.** See kashira-e.

**Pima-Papago art.** The Pima and Papago Indians, kindred tribes, live on the desert plains and mountains of southwestern Arizona, in

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

small villages of mud houses. Some practice agriculture by means of irrigation as did the Hohokam (q.v.), who are thought by some to be their ancestors. Yet they depend upon game and native plants for a considerable part of their food supply. They are masters in basketry, a craft restricted, as in so many of the Indian tribes, to the women. Yucca and seed pods, and the willow, cottonwood and cattails that grow along the rivers supply the materials. The baskets serve a daily use: for preparing, serving, containing and storing food, and for general transportation. They are often smeared with pitch so that they will hold water. Shallow bowls and jars are popular shapes, and the designs, usually dark patterns against a light background, show an astonishing inventiveness in the infinite variation on a few geometric themes. Highly conventionalized bird, human and animal motifs are also used. See Frederic H. Douglas, *Pima Indian Coiled Basketry,* Denver Art Museum Leaflet No. 5 (1930); O. T. Mason, *Aboriginal Basketry,* 1902; Frank Russell, *The Pima Indians,* Bureau of American Ethnology, Annual Report No. 26 (1908). —H.G.

**pinakotheke.** In ancient Greek times, a room or building in which paintings were displayed.

**pine.** See SYMBOLISM IN FAR EASTERN ART.

**p'ing chang** (Ch.). Sets of paintings to be hung together, such as a set of the four seasons.

**pinnacle.** *Arch.* A small, decorative, upright member on top a tower, buttress, etc.

**pins.** *Cer.* Burned fire clay supports for ware in glossed saggers. See CERAMICS I.

**pinxit, pinx.** A term added to the name or initials of an artist on a painting or printed copy of the painting. Means literally that the artist indicated painted the picture or copy.

**p'i 'pa.** See MUSICAL INSTRUMENTS.

**pipal tree.** See bodhi tree.

**pipe.** See MUSICAL INSTRUMENTS.

**pipe clay.** See ball clay; kaolin.

**pique.** Cotton fabric in white or colors with raised cords or welts running lengthwise. May be silk, rayon or acetate. Knit constructions may give similar effect. —G.W.R.

**pir** (Ar.). A monumental tomb. See ISLAMIC ART.

**pirouette** (Burgundian: *pirouette,* spinning top; or Fr. (?) *pied-roue,* foot wheel; It. *pirolle,* peg or pin). The complete spin or turn of the dancer's body, usually in one place, on one foot, elevated high on the half-toe, either fast, or less frequently, slow, in sequence from one to eight or more. —L.K.

**Pisan architecture** seems to be based on types of Byzantine basilicas with galleries and enormous cross transepts (Pisa, cathedral, 1063 ff.. In 12th cent. churches these elements are replaced by a simple basilica plan (without galleries) but the characteristic decoration remains preserved as late as the mid-13th cent.: exterior and interior are incrusted with black and white marble stripes, the façades are decorated by a series of dwarf galleries supported by marble columns, and capitals and bases go back to forms of Roman antiquity. See Salmi, *L'architettura romanica in Toscana,* 1928. —R.K.

**pišarka.** See CZECHOSLOVAKIA, ART OF.

**pisciform.** Fish-shaped.

**piscinum.** See EARLY CHRISTIAN ART.

**pit.** A natural or artificial cavity in the ground or given level.

**pitch.** Highness or lowness of tone, depending on the number of air-vibrations per second. See ACOUSTICS; NOTATION.

**pitch vibrato.** See vibrato.

**pitcher.** A vessel with constricted neck, a handle, and a lip for pouring.

**pit-dwellings, pit houses.** In the American Southwest: A term applied to designate the houses consisting of a circular, oval, or rectangular excavation roofed usually with a truncated superstructure of poles, brush, mud, and plaster, the former occupants of which belonged, at least in the main, to the group of tribes now known as the Basket Makers or Pre-Pueblo Indians. —J.M.M.

**pizzicato.** Plucking the string with the finger. A sound effect, originally employed for harps and lutes, later taken over by all the various stringed instruments in solo and orchestra

**plain song, chant.** See MEDIEVAL MUSIC; NOTATION.

**Plains Indian art.** The Plains Indians occupied an area from the Rocky Mountains to the Missouri River and from southern Canada to northern Texas. Of their more than 30 tribes the more important were the Arapaho, Assiniboine, Blackfoot, Cheyenne, Comanche, Crow, Gros Ventre, Kiowa, and the Western Sioux (Dakota). From a geographically restricted, semi-nomadic, agricultural pattern, dependent upon the buffalo and other animals for food, clothing and coverings, the whole group suddenly evolved a wide-ranging hunting and warrior pattern, largely because of the introduction of the horse by the Spaniard. At their climax, in the 19th cent., they were a nomadic, tipi (q.v.) dwelling people, without basketry, pottery or weaving, possessing only portable objects—even their tipis were portable—and non-breakable rawhide containers. With greater mobility and increasing wealth the Plains Indians gave expression to the art impulse in the decoration of the objects of daily life. With the exception of weapons and carved calumets, or peace-pipes, often decorated elaborately with feathers and hair, all these objects—dresses, shirts, leggings, moccasins, horse-trappings, robes, rugs, carrying bags large and small coverings of tipis and shields—were made from the skins of the buffalo, deer, elk, beaver and other animals, and decorated with quill and bead work, feathers, teeth and claws, fringes and painting. Quill work is an ancient and peculiarly American mode of decoration. Porcupine quills were colored with native dyes, flattened and sewed on the hides in simple geometric patterns. Bead work, of shell, stones and seeds before the coming of the Europeans, became more colorful and more intricate in design with the introduction of porcelain and glass beads from Europe, though still confined to simple geometric shapes adapted to the surfaces to be decorated. The best work belongs to the last quarter of the 19th cent., and styles vary somewhat among the tribes. A dash and flair for dramatic life and a pride in display of material wealth led to elaborate ceremonial costumes with feather headdress and richly ornamented garments and trappings. All this decorative art was strongly geometric except the paintings on skin robes, tipi coverings and shields. Painting was an important art practiced by both men and women but with a strict division of style. Geometric decoration on rawhide carrying bags and containers or on robes was the province of women; while a representative style—hunting and fighting scenes in a lively flat linear style—constituted that of the men. Though these tribes have suffered almost to extinction by the destruction of the buffalo and the advent of the civilization of the white man, a revival of the representative style has produced modern paintings full of characteristic movement and drama. See Denver Art Museum, Dept. of Indian Art, Bulletins: *Plains Beads and Beadwork Designs* (Leaflet 73-74, Dec., 1936), *Parfleches and Other Rawhide Articles* (Leaflet 77-78), Dec., 1936); John C. Ewers, *Plains Indian Painting,* 1939; Carrie A. Lyford, *Quill and Bead Work of the Western Sioux,* 1940; William C. Orchard, *Beads and Beadwork of the American Indian,* 1929; Clark Wissler, *North American Indians of the Plains,* 1912. —H.G.

**plain weave.** See weaving.

**plan.** See design.

**plane of delineation, of measures, of the picture.** See PERSPECTIVE.

**planh.** See MEDIEVAL MUSIC.

**planning authority, board, commission.** See CIVIC PLANNING.

**planographic process.** See PRINTS AND PRINT PROCESSES.

**plaster.** A great variety of materials made up for a variety of purposes carries the name, plaster. Essentially for surfacing the walls of buildings, plaster has been used in the arts as a modelling and casting substance. For such purposes gypsum or plaster of Paris is most common. This has the advantage of recrystallizing or setting by the addition of water and of losing none of its volume in the process. Its tendency to set or harden rapidly can be modified by additions of other materials. Plaster used on walls (see also

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

lime) has served as a ground for painting, the best known being that in the process called "true fresco". —G.L.S.

**plaster of Paris.** See gypsum.

**plastic art.** Changing malleable materials into art products through modelling or molding; generally used in connection with modelling in clay, but in recent years includes working with modern synthetic "plastics" such as celluloid or bakelite. Whiteford and Winslow in *Dictionary of Education*.

**plastic clay.** See ball clay.

**plastic form.** See architectural form.

**plasticizer.** Many of the film materials used as binding mediums for paint or for surfacing or varnishing have a tendency to dry too rapidly and become brittle and friable. In order to reduce this tendency, they have added to them slow-drying ingredients known as plasticizers. For the resins, drying oils and a few semi-drying or non-drying oils have served this purpose. More recently synthetic or chemical plasticizers like dibutyl phthalate and tricresol phosphate have been introduced chiefly for use with the artificial resins. —G.L.S.

**plastic orchestration.** See architectural form.

**plastics.** See resins, synthetic.

**plat, platting.** See CIVIC PLANNING.

**plate.** (1) In construction: A horizontal member, as a timber, placed on walls, etc., usually flat-wise, to receive other members. (2) See ACOUSTICS.

**plate line.** See PRINTS AND PRINT PROCESSES.

**plate mark.** *Etch.* Impression made in the paper, on which a proof is being pulled, by the edges of the metal plate. —K.K.

**plate oil.** *Etch.* A light, medium or heavy burnt linseed oil varnish, used with dry pigments for making the etching ink. —K.K.

**plateresque.** See Mexico, post-Conquest architecture of; FURNITURE; SPAIN, ART OF.

**platform.** Any floor or flat surface raised above the adjacent level.

**platform mound.** See Eastern N. American Aboriginal art.

**play-party.** The play-party (at its height a generation or two ago) was a rural American social gathering for playing games, distinguished by the manner in which it was "got up", by the age of its participants, and by the character of the games played. In its typical form it was not an "invitation affair" but was open to the whole countryside. Attended by the entire family for the same reason that they attended the singing school and the literary society, because they had no other place to go, it had for its active participants the young people of high school and marriageable age and young married couples, with the old folk and the children present chiefly as spectators, although the former might serve as leaders or have their square dances (if they were not conscientious objectors) and the latter might play their own games off at one side or before the regular party began. The most important differentia, however, was the character of the games played. Play-party or party games (to give them their generic name) were, with few exceptions, singing-games, including both dramatic choosing or marching games (which may conveniently be known as "party plays") and dancing games, in which the dancers swung each other by the hands or, if permitted, by the waist, with no music save their own singing ("swinging plays"). Synonyms for the play-party include "party", which meant a play-party as distinguished from a "dance", and "bounce-around" or "frolic" to distinguish the boisterous and rollicking fun of the play-party from the milder diversions of the social or evening party, "social", or "sociable", which was for invited guests and, although it might include swinging plays, was largely restricted to parlor and school games.

Although loose usage has tended to confuse the play-party with any kind of party at which games are played and play-party games with ring-games and singing-games in general, these must be regarded as unwarranted extensions of the terms. And although one might conceivably apply the name "play-party" to picnics and birthday parties at which party games were an incidental feature and from which any or all of the three conditions laid down above might be absent, and although many play-party games have passed into the tradition of the schoolroom and playground, strict usage requires that the term be limited to country or country town gath-

erings of young people from the teens on up, for the sole purpose of playing games with words, tune, dance figures, and dramatic action.

With respect to origins, the play-party game was the natural outgrowth or extension of the traditional game among those who sought a more convenient, well-balanced, and self-sufficient form of rhythmic group movement than either the game or the square dance afforded, one that would combine the best features of both for those who were past the age for the one and yet not wholly content with the other, and one that could be "jumped up" on short notice without the complicated organization that the square dance required, including a good floor, a floor manager, a caller, and musicians. It must not be thought, however, that the play-party arose by any such process of rationalization. Rather, in the nature of things, with the precedent of the singing game before them and the lack of instruments and other facilities for dancing as a motive, the young people hit upon the idea, and once tried and approved, it gained headway and in competition with the dance had to take over more and more of the features of the dance, being kept alive as an independent form and prevented from passing over entirely into the square dance as much by the definite advantages it developed as by church restrictions on dancing. See Botkin, B. A., *The American Play-Party Song*, 1937. —B.A.B.

POETRY. Definitions of poetry begin with the assumption that its subject-matter is clearly delimited and homogeneous. And the single test applied to a work's claim as poetry appears to be its promulgation in this category by the author. The poem may be a bad one, and pronounced "mere verse", but if published as poetry it will be accepted and judged as such. The extreme variety of these productions is recognized and handled by a general division of poetry into kinds, the most fundamental and common such classification being that of *narrative, dramatic,* and *lyric.* Critics, however, agree in their accounts of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

these types only upon a very elementary level. The drama and narrative both connote a story, plot, or course of events where there occur related and progressive actions by human beings; these types are distinguished by the mode in which the events occur: a poem is "dramatic" if the events are told as dialogue or monologue, "narrative" if the story is related by one who does not participate in it. The "lyric" is characterized in a different manner: the traits ordinarily ascribed are reducible to the definition that the lyric is a short, personal, expression of feeling. Because the drama and the narrative both refer to the same element—the form in which the events are related—these types are exclusive. The lyric, on the other hand, is differently defined and, while it may be neither dramatic or narrative, still does not exclude them. Thus we can classify Browning's *The Last Duchess* as a dramatic lyric, and Alfred Noyes's *The Highwayman* as a narrative lyric. The use of these five poetic forms (drama, narrative, lyric, dramatic lyric, narrative lyric) are perhaps adequate to organize into sub-species the complex content of poetry. It does not, however, describe the nature which these several forms, as poetry, have in common.

Definitions of poetry are generally unsatisfactory as designations of the essential trait of the various productions classified as poetry. When such definitions are not merely "literary", that is, serving as the occasion for a striking phrase rather than for serious definition, like Coleridge's remark that prose is words in their best order and poetry the best words in their best order, the characterizations offered are either too broad or too narrow to coincide with what is generally recognized as the extant body of poems. Max Eastman's conclusion that the crucial trait of poetry must be "quality or experience itself" identifies the poetic with at least all aesthetic, and perhaps with all sensuous, experience; whereas Santayana's characterization of poetry as "metrical discourse" excludes many productions usually named poems.

The common element in all of what we ordinarily call poetry is language; but language is not an adequate definition of the poetic, for poetry is distinguished from prose. Of the two elements—meter and metaphor—most generally recognized as essential to a poem, only meter belongs to poetry alone. Literature that we loosely call prose commonly has metaphor as a component. On the other hand, in certain non-metrical literature denominated "poetry", there is to justify this title only the presence of metaphor, which also appertains to "prose".

What seems to have happened is that the use as a criterion of the poetic of *either* of these elements—now meter, now metaphor, and frequently both—has led critics to throw into one category all the multi-colored, multi-shaped things we call poetry. And that for these we cannot find a single definition is precisely because more than one principle has been employed in their selection. For example, it is primarily for the recognition of the element of meter that we consider Aristotle's *Poetics* as a treatise on poetry. While he gives some attention to metaphor and "ornament", Aristotle's obvious concern is with plot structure (which of course may be narrated in prose), and meter is the only pervasive, consistent element linking with recent lyric poetry the dramas and epics which are the primary object of his discussion. On the other hand, among certain metrical lyric poetry and other non-metrical lyrics, the only common element is metaphor. Between the predominantly or exclusively metaphorical and the exclusively metrical poetry there are the poems that contain both meter and metaphor pervasively and essentially; these serve as sort of a bridge extending in either direction to literary expressions that in one case contain meter emphatically but metaphor only at intervals, and in another are essentially metaphorical and possess meter only in such a general, vague way as to have no real correspondence with the quality pertaining to the intrinsically metrical.

Analysis of our use of the term "poetic" and of the composition of what we regard as poetic, discloses that of meter and metaphor it is the latter that constitutes poetry's essence. We may not deny to a creation the adjective "poetic" wherever the metaphor is apt; we may not apply this qualification, however regular the metrical structure, wherever language is not metaphorical. The nature of poetry or metaphor is to be found in an examination of language, which forms the visible substance of poetry.

The function of language is the conveyance of meaning, and meaning therefore is the primary poetic element. But both language and its function poetry shares with prose. Since prose is the proper linguistic contrary of poetry, it is their distinction that sets the terms for the definition of poetry. This distinction resides in their presentation of different kinds of meaning or knowledge. In

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

poetry or metaphor knowledge and meaning become identical, because the meaningful propositions by which knowledge is communicated do not in poetry refer to, or attempt to accurately describe, an externally existing object. Prose meanings refer to externally existing objects. Metaphor uses these prose meanings to compare such objects, discovering therein a *new* meaning or quality, the presentation of which is poetry. *Poetry, then, is the creation of a new quality or meaning through the manipulation of old or prosaic qualities or meanings.* This is demonstrated by a consideration of the nature of knowledge and meaning.

In relation to the world of real objects, knowledge consists in the capacity to compare and distinguish. This function is discovered in the nature of the linguistic symbols by which knowledge is conveyed, perpetuated, extended, and facilitated, if not first made possible in any complex form. All linguistic signs except proper names designate some *general* relation, quality, or kind, "general" indicating that these signs are applicable to a multiplicity and variety of concrete instances. Ultimately to indicate the meaning of a general term is to give its denotation, to point to one of its instances; and since objects are complex, containing many more traits than the one whose particular meaning we are concerned to indicate, it is necessary to point to several objects differing in all respects except in the possession of that trait symbolized. It is clear, then, that if linguistic signs refer to the world of empirical objects —to something directly experienceable—this act of comparison is implicit in the conscious use of any general meanings, and that ultimately knowledge, which is presented in terms of such meanings, is reducible to this act of comparison.

Metaphor makes explicit this to which knowledge ultimately reduces—direct comparison of concrete things, the expression of a quality by physically pointing to those entities which share it. Metaphor resorts to this primitive form of expression because the qualities it wishes to articulate, to give permanent substance to, are utterly original and therefore have not been formulated into a linguistic symbol. If, for example, one wishes to refer to the quality condensed in the established meaning "smooth" it is not necessary to refer to particular objects sharing this quality; but if one wishes to express some variation of quality for which there is no name, he must invoke objects that share the quality. Instead of saying "smooth water-lilies", he will, with Elinor Wylie, say "water-lilies smooth as cream".

Accordingly any attempt to explain a metaphor's aptness is to proceed in the opposite direction from clear perception. As ultimately we can indicate what "smooth" is only by pointing to smooth objects, so must we either realize metaphor in the juxtaposition of the objects it presents, or fail altogether to realize its nature. Our loss to explain why smooth objects are alike in the quality of smoothness is identical with our inability to explain why water-lilies are like cream. The only provocation to look for explanation in the latter instance and not in the former is that smooth is a generally recognized, familiar, qualitative ultimate; whereas this identity between water-lilies and cream is a novel and unique one, not sufficiently recurrent to have been formulated into a word meaning, or a quality resident in, and yet isolable from, many different contexts. Our search for an explanation is really a search for, and must culminate in, a name—a name which we could then give significance only by pointing to the original objects whose identity it expresses.

In our automatic use of language this comparison of concrete entities implicit in the use of general terms and classification into kinds, and explicit in metaphor, is so suppressed that very infrequently do we become aware of the comparative origin and basis of meaning. Paradoxically the only things we are acutely aware of comparing are those that are the least conspicuously similar. We tend to take general classifications for granted, using terms without considering the particular concrete things they designate,—perhaps in the unconscious conviction that whenever the occasion arises we can lay hand to appropriate instances of the kind. But when there is implied or asserted a comparison which we are not accustomed to make and with which we are not familiar, at once we hasten to test it by calling to mind probable objects for comparison. When a term is placed in a relation or ascribed a quality with which it is not habitually associated, then it requires an explicit comparison between the objects so conjoined.

For example, we shall speak of a white house without realizing that thereby we implicitly compare a variety of concrete objects, but when we encounter the phrase "melancholy house" our minds become suddenly alert, evoking live images and vivid comparisons of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

houses to things not obviously similar. The comprehension of "white house" requires no fresh mental effort, for the object house as characterized is a familiar experience; we are accustomed to refer to certain objects as white houses, or to certain houses as "white". The phrase readily evokes an adequate image and the mind traces the path of previous experience. But we are not used to calling houses "melancholy", and since our mental stock does not include the requisite image, we must perform a new mental operation describable either as a putting together of our previous experiences of houses and melancholy things so as to find among the former an instance to which the adjective appropriately applies, or as a fusion of the previously segregated ideas of, and responses to, "melancholy" and "house". However the mental process be stated, the result is a new correlation in which there is presented a certain kind of house (that we have experienced, or can imagine ourselves experiencing) which is more like melancholy things than it is like anything else. Then poetic insight is realized.

This distinguishes the poetic from the prosaic. It is the nature of prosaic meanings to refer to *kinds of things*; it is the nature of poetic meanings to refer to concrete individuals. The culmination of the prosaic tendency is pure mathematics, where the abstracting process has been carried to such degree that but one kind of thing remains, there being no existing object to which the mathematical meanings do not appropriately apply. The culmination of the poetic tendency is an individual experience. In poetry meaning practices self annihilation, perfecting a unique whole relevant to nothing else, speaking to itself, and only *about* itself. The poem is a structure built of symbolic elements referring to classes of things, but which, through the relationship they attain in the poem, exchange their symbolic function of representing, for the substantial one of constituting, an experience. Thus, while in prose, meaning follows its internal bent toward development away from experience (although perhaps—as the instrumentalists insist—with the ultimate object of thereby instituting more satisfactory experiences), poetry turns the abstract back upon itself, and with symbols creates a particular quality.

By taking ordinary signs designating kinds cognitively familiar and therefore used without reference to particular instances, and conjoining them in a way cognitively unfamiliar and actually unexperienced, metaphor creates a new quality, a new experience, and a new kind—even though this "kind" may have but one instance. The comparison of physical things which is the basis for knowledge and its symbols, depends upon the perception of that common element or quality in terms of which comparison is made. In so-called "figurative" language, signs for these qualities, or for objects constituted of a complex of qualities, are so juxtaposed as to elicit a quality distinct from that meant by any component term, and experientially non-existent previously. This seems to happen in the following way: while, in a simple metaphor (as "shadow-rain") the terms employed each refer to an entity or experience in itself prosaic, since alone each would represent a kind, and, assuming no extraordinary personal exercise of imagination, would be apprehended cognitively; the bringing of these prosaic kinds into juxtaposition explicitly *identifies that which had not before been identified* (here rain and shadow), and in this identification creates a quality and kind not before known. In more detail, the process involves the recollection by the reader of experiences of shadows and rain: in the surprise of this unexpected uniting of kinds he swiftly reflects upon and attends to each kind, discovering in his experience or knowledge of these that quality which in each had escaped him until the two were presented together.

The recognition is no different in nature from the insight by which were discovered any of the familiar, general, prosaic (these standing for the same characteristic) qualities that form the substance of practical or facile discourse. We might, for example, imagine a time when there was first recognized that the blue sky and blue sea were both blue, so occurring the identification of blueness in which the quality first became a kind and a name. At such a hypothetical frontier of knowledge "sea-sky" might have served as a metaphor as effective as "shadow-rain". Now, however, "sea-sky" would only be confusing, since we have come to find so many identities in sea and sky that unless told by the context, we would not know whether to look for a new quality or to refer to a familiar, prosaic one; and, if the latter, which of the various identities is intended.

The formal poem is simply an extension of the process and phenomenon of metaphor. If the poem is successful—that is, if it achieves that indispensable condition of all art, unity, then the greater the complexity of content, the more will the number of signs (and kinds)

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

operate to establish a vivid and unique quality. The achievement of the latter does impose limits upon the number and variety of signs (kinds) that can be used. The same sort of limitation is duplicated in the case of the ingredients available to the other arts, namely, the selection of those that can be assembled into an integral whole.

Against this view the following objection might be raised: if a metaphor perfects a unique quality, and since a poem contains several metaphors—each presumably with its unique quality, a poem must consist not of a single quality but of as many qualities as there are metaphors. The objection illuminates the way in which metaphor is embodied in a formal poem. The particular, explicit metaphors of a poem are variations of the single quality of the entire poem, and emerge only as patterns upon its background, or, more exactly, as forms of its substance. We discover how this occurs in searching among poems for metaphors to extract from the poetic body: we find that thus separated they usually lose their meaning. The poem is a whole so closely united that every phrase requires for the expression of its meaning, either all the other lines of the poem, or a certain assembly of lines which together require the remaining poem for their effect. Therefore something is inevitably lost when we lift a metaphor out of a poem, even though in isolation that metaphor may preserve a perfection beyond cavil.

The radical implication of the conception of poetry as essentially metaphor, is that such classical works as Dante' *Inferno,* Milton's *Paradise Lost,* Shakespeare's plays, Homer's *Odyssey* and *Iliad,* are not poems. This does not mean that they are not "greater" (whatever the adjective may mean) artistic works than any poems in the strict sense. To judge this one must determine in what greatness in art generally consists, and just what is the nature of the above productions. It may be that these are greater in that they contain within their non-poetical scope superlative isolated poems. It may be that they are greater as representing a higher type of art, in which poems may enter as contributing elements,—the way drama and music combine in the opera. Or, finally, it may be that they are inferior. All that is insisted is that the poem as here defined does constitute a distinct kind of art and experience, and that it is in the interest of clarity to recognize this even when it involves the reclassification of a vast outstanding body of literature. Following the latter conviction, we have drawn into the body of poetry proper its simple element—the metaphor—rather than taking the traditional path of proceeding from the formal poem to sweep into its category the more extended forms in which this already complex entity serves as a component. The method can strike as objectionable only those who read into it some kind of depreciation of the contributions of the authors enumerated. And indeed that this can occur is only another indication of the need of the term "poetry" for revision. It indicates that the term has acquired a connotation of more excellence, applying as a form of praise, rather than designating simply a type of art, which—like all art—is excellent when successful. **pointed style.** Gothic style.

**pointes** (Fr. extremities). The academic term for dancing on the extended toes (*sur les pointes*), supported by the rigid metatarsal arch, enclosed in satin slippers with a stiff leather shank, the point of contact with the floor strengthened by a small box of cardboard, the toes often protected by lamb's wool. —L.K.

**pointillism.** See PAINTING.

**pointing.** Reproduction in stone of a clay or plaster model by drilling holes to the proper depth in a stone block at points corresponding to points indicated on the model by the sculptor.

**point of distance, of sight, of view.** See PERSPECTIVE.

**pole.** A long slender piece of wood, commonly tapering and more or less rounded; usually five inches or less in diameter.

**police power.** See CIVIC PLANNING.

**polichinelley.** A clown-dance.

**POLISH ART.** *General Characteristics.* Dating from the arrival of Christianity from Rome in 966, Poland has culturally always

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

been closely connected with Western Europe. Thus Polish art always went hand in hand with the evolution of art in Western European lands. Like there, so in Poland do we distinguish the Romanesque, Gothic, Renaissance, baroque, rococo, and classic periods, and the 19th and 20th cent. multiple art movements.

Foreign influences that reached Poland from various Western European countries were by no means limited to a single source of origin; they came from Bohemia, from Italy, from France, the Netherlands, and Germany. But in spite of the parallelism in the development of Polish art and that of the entire West, certain characteristics took root in Poland more easily than others. Moreover, guided by native predilections and inspired by the native temperament, Polish artists tended to modify the adopted forms of art.

In architecture, e.g., the local variations of the different Western European styles were brought about by climatic conditions, by the character of the landscape and that of the building materials abundant in Poland—wood or brick—, and last but not least, by the fact that the builders, even when the architectural designers were foreigners, were mostly local people accustomed to the particular features of the wooden Polish dwellings, the sources of which might be traced back to wooden architecture of prehistoric Poland, and which partly survived until the present day in the peasant's huts.

On the other hand, Polish painting, while from its inception characterized, in common with Western art, by naturalism, often shows certain decorative tendencies in respect to form, and a lyric and pensive mood as regards inner content, both features held in common with Byzantine-Russian art. One may easily understand, however, that by reason of its interest in nature, the form as well as the content of Polish art are richer than those of Byzantine-Russian art, which is essentially imaginative, refusing to model itself upon forms seen in nature.

The decorative qualities of Polish art, esp. noticeable in the applied arts, were in later centuries encouraged by the growing Islamic influences, which brought with them a wealth of ornamental designs. Particularly welcome seemed to be the floral motifs which have been fruitfully combined into new patterns with the indigenous motifs of more naturalistically conceived flowers, a most beloved element of all Polish peasant art, be it old or new.

No doubt also the general Polish fondness for clear, vivid, yet always harmoniously arranged color schemes has its roots in indigenous Polish peasant art.

In the art of Poland, native and foreign elements now exist side by side on a separate and even hostile footing, now they intertwine and mingle. At times, the decorative traits and the vivid color harmonies in Polish art generally, and the tendency toward pensiveness in painting and sculpture specifically, appear only in works of art produced away from the art centers by local artists who had only an indirect or casual contact with the great art currents of contemporary Western Europe; at times, however, they victoriously shine through the pan-European forms as created by Polish artists well acquainted with the art evolution abroad, who notwithstanding, did not lose their national individuality. Finally, let us still mention that as a rule the Polish national characteristics appear most distinctly in the decorative arts.

*The Romanesque Period.* To the oldest Polish architectural stone relics belongs the *St. Felix' Church,* a small rotunda, not so long ago excavated on the *Wawel Hill* in Cracow, and dating from the beginnings of the 11th cent. During this and the following century a number of monumental Romanesque cathedrals and monastic churches was erected in Poland. Among the Polish most remarkable Romanesque sculptures are the famous bronze doors (ca. 1127) of the Gniezno Cathedral. These doors are ornamented with bas-reliefs representing scenes from the life of St. Adalbert, patron of Poland. Twelfth-century chalices and other accessories used in divine worship, preserved in the treasuries of many Polish churches, are engraved with scenes closely related in style to the Gniezno doors and bear witness to French influences, then predominating in Poland.

*The Gothic Period.* By the middle of the 13th cent. the Gothic style was spreading throughout Poland. Soon it acquired distinctive local features. The Polish modification of the Gothic architectural style is known as the **Vistula Gothic.** Its clear formulation was achieved by the middle of the 14th cent. and its most mature representative is the *Church of Our Lady* in Cracow (1226-1442). The Vistula Gothic is characterized by the use of brick for the walls, stone being used only for the constructive and decorative parts. The brick walls, while lofty, are massive and solid. Thus the buttresses are directly in contact with the walls and are not reinforced

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

by a second row of flying buttresses and auxiliary arches, so typical of the French Gothic. The windows, while having pointed arches, are relatively small. The churches thus often bear resemblance to fortified castles. Multi-colored bricks, arranged in decorative patterns, enliven the outdoor surfaces; frescoes the interior walls.

Polish Gothic wooden sculpture, which reached a high degree of perfection during the 14th and 15th cent., is marked by deep expressiveness. Religious in kind and destined for the churches, it developed in cities, where artists and craftsmen were organized into guilds. The attempts at realism, noticeable during the latter part of the 15th cent., received a powerful impulse by the creative work of Wit Stwosz, or Stosz (ca. 1445-1533), in German called Veit Stoss, an artist claimed both by Poland and Germany. Among the many masterpieces executed by him in Cracow, where he spent the best years of his life, at least the gigantic wooden polychromed altar piece (1477-1489) at the Church of our Lady ought to be mentioned. The influence of Wit Stwosz on Polish sculpture lasted far into the 16th cent.

Polish Gothic painting is represented by numerous altarpieces, mural decorations, as well as illuminations. It reached the peak of its evolution during the 15th cent. A gem of Polish Gothic painting is, for instance, the *"Deposition" of Chomranice* (middle of the 15th cent.), at the Tarnow Museum. In this and other Polish Gothic paintings one may observe, despite strong foreign influences, a greater emphasis upon decorative detail than in the West, a leaning to a harmonious arrangement of a few but saturated colors, a special fondness for gilding; one may further note that the faces of the human figures are, like those of Polish contemporary sculptures, strongly imbued with feeling and lyric mood.

While the names of the Polish guild painters chiefly remain anonymous, let us mention Jan Polak, painter of Polish origin, a leading master of the Bavarian school from the end of the 15th cent.

Of many highly accomplished contemporary miniatures and illuminations, those illustrating the *Codex of Baltazar Behem* (ca. 1505) are worthy of special attention, as they represent the activities of the flourishing Gothic craftsmen's guilds.

Also woodcut, copper engraving, and stained glass reached a high degree of perfection during Poland's late Gothic period.

*The Period of the Renaissance.* The Italian Renaissance was introduced in Poland by King Zygmunt (Sigismund) I (1506-1548) and is often referred to as the **Cracow Renaissance.** This king entrusted the rebuilding of the medieval royal castle on the Wawel Hill at Cracow to an architect known in Poland as Franciszek Wloch (*Wloch* meaning "the Italian"), who constructed a three-story colonnade of arcades around the castle's courtyard (1502-1516). Another Italian, Bartolomeo Berecci, built the much admired *Sigismund Chapel* (1517-1533), in the medieval Cracow Cathedral on the Wawel.

Following the example of the king, many Polish notables and Polish towns summoned architects from Italy to erect or rebuild castles and townhalls according to the laws of the Italian Renaissance. However, these architects soon succumbed to local influences. They enhanced the picturesqueness of their buildings by adding certain architectural details, especially placing high ornamental galleries over the top stories. These fanciful galleries soon became a typical feature of Polish Renaissance buildings throughout Poland.

Above all, dwelling houses in small towns developed a late Renaissance ornamental style of their own, still flourishing at the beginning of the 17th cent. The houses in Kazimierz-on-the-Vistula provide a good example of this style. Besides the crowning galleries, they have façades all covered with multiple linear decorations. At the same time, a modified Gothic style still was alive in small wooden country churches.

The evolution of Polish Renaissance sculpture may best be followed in sepulchral monuments. Of the Italian sculptors carving tombs in Poland, Giovani Maria Padovano, was the most influential toward the beginning of the 16th cent.; of the Polish, Jan Michalowicz of Urzedow, active from 1553 to 1582. He gained the surname of the *Polish Praxiteles* for himself.

While 16th-cent. Polish architecture and sepulchral sculpture both enjoyed the patronage of the Polish kings and notables, wooden church sculpture and painting as well as all kinds of crafts remained in the hands of the guild masters, who held more or less fast to the traditions of the Polish Gothic. Especially in provincial towns painting and sculpture became only slightly touched by the new currents. Nonetheless, the guilds produced many a true masterpiece during the first half of the 16th cent.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

But by the middle of this century the guilds, deprived of the protectorate of the wealthy, began to decline. Still, for many decades to come, they created throughout the country religious works of art which, although to a certain extent primitive in character, excite our great interest as Polish art manifestations completely deprived of direct foreign influences. In this city guild art the national characteristic features were manifested more freely and more distinctly than in other, more mature but less independent trends of Polish art of the time. Thus, for instance, the Polish guild paintings of the period are marked by a decorative quality, forming a counterpart to the façades of the contemporaneous small town houses, by a naïve but refreshing sincerity of expression, and by harmoniously contrasted colors, having no half-tones but local values. A most distinctive specimen of this popular national trend in Polish art is the *St. Martin* in one of the altars of the Poznan Cathedral, painted in 1628 by Krzysztof Boguszewski.

Of the Polish artists of the period who attained success abroad, Jan Ziarnko of Lwow, known also as *Il Grano* or *Le Grain*, is the best known. An outstanding draughtsman and engraver, he was active toward the end of the 16th and beginning of the 17th cent.

*The Baroque and Rococo Periods.* Notwithstanding the traditional tendencies of Polish provincial art, the Italian baroque architecture found its way to Poland very early, which is witnessed by the *Church of SS. Peter and Paul* in Cracow, built in 1597-1619 by Gian Maria Bernardone and J. Trevano, greatly inspired by the *Il Gesù* in Rome. Italian baroque churches soon became popular in Poland. By the end of the 17th cent. and at the beginning of the 18th certain local innovations were introduced. Along with an ornamental treatment of the façade, an exuberance of sculptured interior decoration became characteristic. This style reached a particularly high level in 18th-cent. churches of Wilno and Lwow, famed for their rococo decorative sculptures.

The baroque also influenced the style of the Polish palaces. Also here it soon appeared under a polonized form, which may readily be recognized in the royal palace at Wilanow (1677-1694), the favorite residence of King Jan Sobieski, built by an Italian under the king's personal supervision. The Wilanow palace stretches wide and low like the Polish noblemen's wooden country mansions, they themselves being an enlargement and enrichment of the simpler peasant dwellings.

From the middle of the 17th cent. until the end of the 18th the inter-European trends in sculpture and painting came to be represented almost exclusively by foreign royal court painting and that developing at the palaces of the Polish aristocracy and in some wealthier monasteries. This foreign painting acquired such an importance that it gave no chance to develop even to the more popular paintings of the guilds. Nonetheless, native art did not die out: It withdrew to the peasants' quarters.

Here must first of all be mentioned the vivid yet harmonious decorations consisting of stylized flower motifs, which often covered the walls and ceilings of the 17th-cent., and also earlier peasant wooden churches. Besides, there exist intimations that it was toward the end of the 17th cent. that the Polish peasant woodcuts, which came to full bloom more than one hundred years later, made their first appearance. These religious woodcuts, similar to the figures of saints carved in wood by the peasants to be placed in wayside shrines, combine traditional Polish Gothic elements with those of the baroque and rococo styles. Both the peasant carved figures and woodcuts, strikingly expressive, attained a high degree of beauty within their primitive forms.

Also the beginnings of the peasant kilims and of tapestry weaving—the latter usually executed in country manors but most often with the help of peasant craftswomen—seem to have occurred in Poland during the 17th cent. The peasant *kilims*, which flourished during the following two centuries, clearly show a merging of typically peasant, freely treated flower patterns with some geometricized Oriental designs.

It must be emphasized that it was just during the baroque and rococo periods that strong Islamic influences invaded Poland, bringing with them, besides direct Turkish, very numerous Persian elements, which left an impression on contemporary Polish textiles, the nobleman's dress and his arms and armor.

*The Classic Period.* The second half of the 18th cent. witnessed a flowering of Polish art comparable in kind to that during the Cracow Renaissance. The center of this flowering became Warsaw, the new capital of Poland; the great protector of the arts being the last king of Poland, Stanislaus Augustus

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Poniatowski. *The Royal Palace in the Lazienki Park* in Warsaw, built and decorated in 1784-88 by Italians in strict co-operation with the king, is the most outstanding example of the Polish late 18th-cent. classicism, known as the **Stanislaus Augustus style**, combining French rococo reminiscences with predominating Roman Palladian elements. The famous interiors of the often reconstructed Royal Castle in Warsaw, often referred to as to *Zamek* (which means castle), were executed in the same style.

This Warsaw classicism, when reaching other Polish towns and cities, underwent through local changes. In Wilno, where one of the most eminent Polish architects of all times, Wawrzyniec (Lawrence) Gucewicz (1753-98), was active, it acquired an almost Grecian purity of style. The Wilno Cathedral may be proof of it. Many other Polish architects distinguished themselves during the Stanislaus Augustus period.

The most influential of the numerous French and Italian painters, sculptors, and interior decorators working for this king, was the Italian Marcello Bacciarelli (1731-1818), a talented portraitist and author of the large historical paintings decorating the Warsaw Castle's walls. But it was the French painter Jean Pierre Norblin (1745-1830), not employed by the king but by one of the Polish notables living outside of Warsaw, who became best known of all the foreign artists who at the time found bread and fame in Poland: He was the first to introduce Polish genre motifs into painting and thus became the forerunner of a large number of Polish 19th cent. artists devoting their talents exclusively to Polish country scenes.

On the other hand, the Pole Tadeusz Konicz, or Kuntze (1733-93), became noted for his genre scenes illustrating the life on the streets of Rome, where he spent most of his creative years. Of the many other talented Polish late 18th-cent. painters Franciszek Smuglewicz (1747-1807) was the most outstanding representative of the current inter-European pseudo-classic trends.

In the field of the decorative arts, wide silk sashes profusely interwoven with gold and silver became world famous. A striking feature of the Polish nobleman's costume, they attained a style of their own by the end of the 18th cent., thanks to a skilful merging of Near Eastern and Western elements with indigenous peasant flower motifs. Produced in workshops scattered throughout the country, these sashes are often termed the **Sluck sashes**, as the workshop in the town of Sluck was one of the most prolific.

*The 19th Century.* At the beginning of the 19th cent. Polish architects produced many a beautiful building reminding one of the severe classicism of the late 18th cent. Wilno school. Then, like in all Europe, so also in Poland, the different "historical" styles followed. Similar trends might have been noticed in 19th cent. sculpture, and still more in the decorative arts. It was chiefly in painting that the creative spirit of the Polish nation expressed itself freely during the past century.

The tragedy of the Polish partitions toward the end of the 18th cent. and the simultaneous development of new social ideas centered the attention and emotions of the Polish people upon their country. Thus during the entire 19th cent. the subjects of the Polish paintings were in one way or another connected with the life of the nation. Yet, while a large number of the Polish paintings from the first half of this century represented important moments from Polish history, in style they corresponded to current Western European art. With the exception of Henryk Rodakowski (1823-94), adherent of the progressive French coloristic school of his time, most of the Polish portraitists and historical painters followed the path of pseudo-classic art as already Franciszek Smuglewicz had done.

It was only during the latter part of the past century that Polish historical painting became more distinctly national in character, but even then not so much in respect to outer form as to inner content. The decisive step in this direction was made by Jan Matejko (1838-93). His historical canvases, while conceived in the style of the contemporary romantic school, are famous for their dramatic intensity, for their strength and depth of expression, for the power of feeling emanating from the figures which he created. The pensiveness of certain personages which had been here and there noticeable in the religious pictures from earlier times, or even in the historical pictures of Matejko's immediate predecessors, grew in the hands of this great master to a strength of feeling which became an integral part of his works.

A close contemporary of Matejko, Artur Grottger (1837-67), pupil of the Vienna Academy, represented the sad scenes from the Polish insurrection of 1863, the tragic life of the political prisoners, and the Polish widows and orphans, endowing his drawings

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

with truly poetic and lyric qualities. Jacek Malczewski (1855-1929), a symbolist, was greatly inspired both by him and by Matejko. Let us add that generally in all art that followed Matejko and Grottger, even up to the invasion of Poland in 1939, i.e., in realistic, impressionistic, cubistic, formistic, and neoclassical trends—sadness, melancholy, and pensiveness come to the fore as characteristic features of the inner content of the Polish paintings. Lyric mood has become the chief ingredient even of landscapes.

Along with the development of 19th-cent. Polish historical painting, another line of evolution may be followed in the creativeness of artists who took the road opened by Norblin. First of all, Alexander Orlowski (1777-1832), world-known caricaturist of Polish types and manners, who later settled down in Petrograd, and Piotr Michalowski (1800-55), a splendid painter of horses, the *Polish Géricault*, must be mentioned. Another excellent draughtsman of horses was Juliusz Kossak (1824-99), to a large extent self-taught, who began to show the picturesque life of the Polish nobleman, at the battle, at the hunt, and on the ride. He gave inspiration to a large number of Polish artists of the end of the century, who, like himself, placed accent on the picturesque side of the life of the Polish spirited country gentleman of their own and bygone days. Jozef Brandt (1841-1915), a disciple of the realistic Munich school, was their leader.

Finally, other artists began to depict the life of the Polish peasant and the Polish landscape. Jozef Chelmonski (1849-1915), a realist and a famous painter of horses in his youth, became in his later years a poetic interpreter of the Polish lowlands. After him came numerous other landscapists led by Julian Falat (1853-1929) and Leon Wyczolkowski (1852-1937), chief representatives of the *Polish impressionism*; while Alexander Gierymski (1849-1901) and Jozef Pankiewicz (1866-1940) were ardent adherents of the French impressionism.

Of the graphic arts, lithography and etching came to full bloom during this period.

Owing to the creativeness of the Polish impressionists, the Polish national features of form once again—after a long absence—found their way into art of a general European character. Yet even in Polish impressionistic painting the native form elements came into view only sporadically and not always in full. Here and there a distinct tendency to decorativeness became visible, elsewhere a clear, vivid arrangement of colors appeared. But these features neither occurred simultaneously nor did they strike by their distinctiveness. They fought for existence with the more or less predominating features of current French art.

The national Polish elements of form appeared much more distinctly in Polish decorative painting of the time. Jan Mateiko—who, as has been pointed out before, introduced into his historical canvases Polish inner content but remained faithful to the Western European style as outer form was concerned—gave toward the end of his life the principal incentive to the development of a national form in modern Polish mural decoration. The beginning of a splendid evolution in this field was made by the polychromy with which Matejko, aided by Stanislaw Wyspianski (1869-1907), painter, interior decorator, as well as poet, and Jozef Mehoffer (b. 1869), decorated the vaults and walls of the famous old Gothic *Church of Our Lady* in Cracow. This decoration brought in, along with some ornamental Gothic motifs, certain floral designs and stylizations peculiar to peasant creations. These latter designs triumphed in the church polychromies and esp. stained glass windows created by Wyspianski and Mehoffer during the time of their artistic maturity. Mehoffer, who outlived Wyspianski for several decades, gained international renown thanks to his gorgeously beautiful windows designed for the Fribourg Cathedral in Switzerland. He worked on them since 1894 for thirty years.

Both these artists were, together with the Polish impressionists, members of the art society **Sztuka** (Art), which, founded in 1897, was active until the very last days of the independent Republic of Poland. This fact explains the lasting influence of all these artists on modern Polish art. Their influence was enforced through their educational activity: In 1895, two years after the death of Matejko, Julian Falat, one of the leaders of the Polish impressionists, became director of the Cracow School of Fine Arts, reorganized it into an Academy, and, inviting most of the progressive Polish artists of his time as professors, made it the most radical Academy of Fine Arts in Europe of the end of the past century.

*The 20th Century.* THE FINE ARTS. It was the versatile genius Stanislaw Wyspianski (cf. above) who, during a period of international eclecticism in architecture, turned his attention, and that of his generation, to the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

beauty of the wooden homesteads and churches built by the Polish peasants and foresaw how these peasant architectural forms could be applied to monumental buildings and could help to create a national style in modern Polish architecture. However, this great artist's efforts brought true results almost two decades after his premature death. These results could be seen in the modernistic style of architecture of the restored Polish Republic. In this modernistic Polish architecture two tendencies were distinctly apparent: one marked by strict adherence to the so-called *international* (q.v.) style, so widely adopted in France and in the Netherlands; the other characterized by an effort to combine rational modern forms and new building techniques and methods with architectural and decorative elements peculiar to Polish peasant wooden buildings. This modern national architectural style found its purest expression in the Polish Pavilion built from the plans of Jozef Czajkowski (b. 1872) for the International Exhibition of Decorative Arts in Paris in 1925.

During the evolution of Polish architecture that followed, an increasing tendency toward blending of modern architectural forms with a neo-classical monumental style was to be observed. Bohdan Pniewski was one of the foremost representatives of this tendency.

Ksawery Dunikowski (b. 1876) was the strongest personality in sculpture of reborn Poland. He created works in stone for architectural decoration of a distinctly monumental character. Among his contemporaries, Stanislaw Ostrowski (b. 1878), an excellent portraitist, remained faithful to impressionistic art, while Edward Wittig (1877-1940) represented the more advanced international tendencies in modern sculpture. In contrast to Wittig, Jan Szczepkowski (b. 1878) drew his chief inspiration from the woodcarvings of the Polish highlanders of the Podhale Valley—with the village of Zakopane as its artistic center—situated on the northern slopes of the Tatra Mountains.

These artists were followed by a number of very talented younger sculptors, each of whom found an individual way of expression within the modern sculptural style. Among the many, at least Henryk Kuna (b. 1883), August Zamoyski (b. 1893), Stanislaw Szukalski (b. 1895), and Alfons Karny (b. 1901) ought to be mentioned.

In painting, the first two decades of the 20th cent. may be considered the years of triumph of the Polish impressionists. However, between 1917 and 1922 Polish artists instigated by modern anti-naturalistic trends and organized into the society of the **Formists** were passionately protesting against the art of the Polish impressionists. Tytus Czyzewski (b. 1884) was one of the leading painters of the new group, and Zamoyski, the most outstanding sculptor. The Polish formists were affiliated with the French cubists, placing, however, a stronger accent on color and its expressive qualities in their paintings. While some of the formists remained faithful to their ideals during all their creative years, in time many others returned to nature as the source of their inspiration.

Already in 1922 another artistic group, called **Rytm** (Rhythm) was formed. A rhythmically arranged composition of their paintings was the common aim of the *rhythmicists.* Tadeusz Pruszkowski (1888-1942), an outstanding colorist, was the most popular among them; Eugene Zak (1884-1926) formed the link between the modern Parisian school and the members of the group. Kuna and Wittig represented best the sculptors.

Closely related to the founders of the *Rytm* society was Ludomir Slendzinski (b. 1889) of Wilno, a decided linearist of neo-classic predilections, who was the head of the flourishing **Wilno Neo-classicist School.**

Of art societies formed by younger painters the **Komitet Paryski** (Parisian Committee), called also **K. P.**—whence its members became known as **Kapists**—is of great interest. Zygmunt Waliszewski (1897-1936) was one of the leaders of this group. Pupils of Jozef Pankiewicz—a splendid colorist who first adhered to the French impressionism and later consecutively to the more progressive Parisian movements—the *Kapists* inherited a love of color and of modern French art from their master. Thanks to these preferences they were in many ways closely related to the Polish formists.

On the other hand, both the **Brotherhood of St. Luke** and the so-called **School of Warsaw** took as a possession some of the ideals of the *rhythmicists* and the Wilno neo-classicists. The *Brotherhood* was organized in 1925 by former disciples of Tadeusz Pruszkowski, Professor at the Academy of Fine Arts in Warsaw. In accordance with their old-fashioned name the founders of the *Brotherkood,* as for instance Boleslaw Cybis (b. 1899), were zealous students of old masters, especially in so far as the technique of painting was concerned. *The School of Warsaw,* composed of somewhat younger graduates of Professor Pruszkowski's class, placed greater

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

emphasis on color than did the others. Finally, let us add that while Zakopane was the favorite summer resort of artists grouped in the *Sztuka* society, the younger generations of Polish painters felt increasingly attracted by the old picturesque little town of Kazimierz-on-the Vistula.

Although in all the work created by the various Polish painters of independent Poland typically lyric tendencies found an adequate expression and scattered elements of national form might have been easily recognized by the eye of an art connoisseur—yet again, like several decades before, the national outer form appeared in a unified and condensed manner only in decorative painting. As time went on the followers of Mehoffer and Wyspianski began to seek national motifs in peasant art more and more consciously, realizing that this art had remained almost untouched by alien influences. This turning of the newer Polish art toward the folk primitive corresponded to analogical movements in other countries where, for instance, cubists, expressionists, futurists, infantilists—as well as the Polish formists—also sought inspiration in the simple and expressive art of the various manifestations of the primitive.

In sculpture, this development came to full flower in the decorative wooden bas-reliefes of Jan Szczepkowski; in painting, in the striking mural decorations and book illustrations of Zofia Stryjenska (b. 1894), which are Polish in line, color, and composition, Polish in their spirited vigor, not devoid of lyric and romantic notes. At the same time, her manner of stylization, her form tending to strong simplification, rejecting all detail and concerning itself only with the basic and the essential, gives her work qualities which characterize all modern progressive art. Thus Stryjenska's decorative paintings, while being distinctly Polish, are at the same time universal in character.

The initiator of a similar trend toward folk art in the Polish graphic arts was Wladyslaw Skoczylas (1883-1934), Poland's leading wood engraver, who very strongly based his art on national traditions as manifested by the Polish peasant woodcuts. In 1926 he founded a society of Polish graphic artists, mostly wood engravers, called **Ryt** (Engraving). The artists grouped in the *Ryt* were able to unite in a most masterful manner the native qualities of the Polish peasant woodcut with the international so-called modernistic principles of composition and drawing. Of these artists Stanislaw Ostoja-Chrostowski (b. 1897) became best known abroad.

THE DECORATIVE ARTS. Poland participated vividly in the 20th cent. revival of handicrafts in Europe, the more so as the Polish decorative arts found an additional impulse in the peasant crafts which had not lost their integrity even in face of the 19th cent. eclectic styles and the still more threatening 19th cent. mass production.

To create a Polish style in interior decoration, Polish 20th cent. artists turned to the peasant's hut for inspiration. They learned from the peasant themselves to handle tools and were reminded by him of the golden rule of long past centuries that form must logically be related to its medium and function. In consequence they rejected the eclectic imitations of various historical styles and replaced them by forms subordinated to the material used and to the utility of the objects created. Moreover, the professional artists introduced many of the peasant's traditional ornamental motifs into their art, all in all achieving a purely national style.

The first contact of professional Polish artists with Polish peasant art occurred at least thirty years before the time of Poland's liberation, when a handful of artists and writers "discovered" Zakopane and the arts and crafts of the Podhale highlanders. As years went by, the professional artist's understanding of the Polish peasant art became deeper and his own art more mature and more convincing. A year before World War I a society was founded in Cracow, called the **Cracow Workshops**, which became a laboratory for many artists inspired by the peasant handicrafts. One of the chief promoters of the new movement in Polish decorative arts was Jerzy (George) Warchalowski (1875-1939).

When at the International Exhibition of the Decorative Arts in Paris in 1925 restored Poland had her own pavilion and participated in a number of special international expositions, the national character of the Polish exhibits was universaly recognized. They received 189 rewards, among them 36 *Grand-Prix*, 31 diplomas and 60 gold medals. The fame of Polish interior decoration and applied arts has been established since. The arrangement of the Polish section at the Paris International was under the able supervision of Warchalowski. Among the artists who bene in charge of the interior decoration of the Polish section, Jozef Czajkowski the designer of the entire Pavilion, Wojciech Jastrzebowski (b. 1884), and Karol Stryjenski

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

(1890-1935), all three since Poland's regained independence professors at the Warsaw Academy of Fine Arts, had been Warchlowski's collaborators already in the *Cracow Workshops* of pre-war times. So were Jan Szczepkowski, the carver of the wooden chapel at the Exhibition, Zofia Stryjenska, the painter who executed the now world-famous decorative panels for the main hall of the Pavilion, and last but not least, Jozef Mehoffer, renowned creator of stained glass windows. Among the latter artist's work for reborn Poland first of all the stained glass windows for the Wawel Cathedral in Cracow ought to be mentioned. Two of these were shown in Paris in 1925.

Along with the above-named artists many others contributed to the success of the Polish sections at the Paris Exhibition. Books, beautifully illustrated by Stryjenska, Skoczylas and a number of other prominent artists and covered in attractive book-bindings, bore witness to the high level of the art of bookmaking in modern Poland. Expressive figures carved in wood by pupils of the *State School for Wooden Industry* in Zakopane gave proof that the Polish style, based on the peasant's age-long traditions, has also captivated the Polish artistic youth.

Among the specimens of the Polish applied arts at the Paris Exhibition, embracing furniture, toys, posters, textiles, etc., it was the *kilim* which at once occupied the first place artistically. Outstanding Polish artists had been drawing their creative inspiration from the old peasant kilims. However, they treated them creatively, bending their ornamental motifs and color harmonies to modern stylistic trends and to the demands of the modern technique. The most beautiful Polish kilims were produced by Bogdan Treter and by the aforementioned Jozef Czajkowski and Wojciech Jastrzebowski.

Also members of the Warsaw co-operative society of decorative arts for the interior, called Lad, which means *order* or *harmony*, became famous for the kilims they produced. The *Lad* was founded in 1926 through the initiative of the creators of the Polish sections at the Paris Exhibition, in close cooperation with their pupils, representatives of the post-war generation of artists. The *Lad* also produced outstanding textiles made of flax, and more recently also of silk cultivated in Poland, and generally objects of great beauty in all fields of the applied arts.

During the last years of Poland's independence, a development in the field of furniture, ceramics, and metal work became noticeable. Graceful pieces of furniture, characterized by fluent and soft lines, agreeably shaped earthen vases and figurines as well as all kinds of metal adornments, such as buckles, bracelets, and belts, attracted the attention of many a visitor of the Polish Pavilion at the New York World's Fair, 1939-40.

The many handsome speciments of Polish decorative arts created during the last few years of Poland's independence and exhibited at this Fair, harmoniously blended Polish native taste with modernistic trends of present-day art, and even with those of past centuries—without, however, any detriment to the national character of the Polish arts and crafts.

The same style was the dominant feature of the interior decoration of the Polish transatlantic liners, especially of the *MS. Pilsudski*, built in 1935 and torpedoed in 1939, and of the *MS. Batory*, built in 1936. The interiors of these beautiful passenger ships perhaps represented the most mature achievements in this domain of Polish art. The decoration and furniture of the ships were designed and executed by a number of first-rate Polish artists under the able direction of Stanislaw Brukalski (b. 1894) and Lech Niemojewski (b. 1894), architects, Wojciech Jastrzebowski, the previously cited decorative artist, and Tadeusz Pruszkowski, the influential Polish painter. It is characteristic that on this as on other Polish art projects, artists of all branches of Polish art strictly co-operated, no distinction being made between those who represented the so-called fine arts and those devoting their talents to the decorative arts. In modern Poland both fields of art were considered to be of equal artistic importance.

ART EDUCATION. Although the stylistic evolution of any art follows its own, innate rules, independent of social and political happenings within the country, yet a proper care given to art by all who influence the education of the nation may contribute immeasurably to the results obtained. In modern times the responsibility for the protection of the arts chiefly rests in the hands of the governments of the countries. In subdued Poland, private individuals sponsored art schools. But as soon as Poland regained her independence, the new Polish government took art into its protection, reorganizing the existing and founding a number of new art schools.

Among the art schools, the Academy of Fine Arts in Cracow should be mentioned first,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

being the only one already in existence before World War I, thanks to a relative freedom that Cracow had enjoyed under the Austrian rule. The professors of the Cracow Academy belonged to the most eminent representatives of the Polish impressionistic movement; many of them were active as art educators until the last days of Poland's independence. Since 1925 the Academy of Fine Arts in Cracow had its branch in Paris with Jozef Pankiewicz as its head.

In contradistinction to Cracow, before the re-establishment of free Poland Warsaw, under sterner Russian rule, had only one school of fine arts, which was supported by donations and private contributions. But this school, reorganized and opened by the Polish government as the *School of Fine Arts in Warsaw* and soon afterwards bestowed with the title of *Academy,* became the center of the modern art movement in Poland. It may suffice to remind the reader that a number of renowned art societies—for instance, the *Brotherhood of St. Luke* and the *School of Warsaw,* both embracing painters, the *Ryt,* embracing graphic artists, the *Lad,* devoted to the decorative arts—were founded by professors and graduates of the Warsaw Academy. Other Polish art schools on an academical level in independent Poland were the *Faculty of Architecture* at the *Warsaw Polytechnic Institute* and that at the *Lwow Polytechnic Institute* and the *Faculty of Fine Arts* at the *University of Wilno.*

Along with the academical schools of fine arts, professional schools of arts and crafts were of great importance in the development of art in Poland. Of these the most significant were the schools at Cracow, Lwow, Poznan, Warsaw, Wilno, and Zakopane. It should also be noted that the Academy of Fine Arts in Warsaw, the most progressive art school in Poland, embraced important departments of the decorative arts, considered by this Academy to be as important as the departments of the fine arts. This introduction of the study of decorative arts by an academy of fine arts was logically consistent with the modern Polish principles of art education. These new education methods affected in one way or another all Polish art schools, the elementary as well as the academical, and were best evident in the professional schools of arts and crafts.

The new system of art training in Poland was based on Polish art traditions and Polish peasant art, at the same time, however, following the most progressive principles of art education in Europe. When Poland regained her political freedom after World War I, she had many artists who for years previously had studied privately the working methods of the peasant and had learned from him to work directly in the medium used and create their designs as they fashioned the material. The most eminent among these artists became leaders of art education in modern Poland. Thus, while before the liberation of Poland in official schools of decorative arts the chief accent was placed on copying from nature and the study of historical styles, in free Poland the art students were taught how to handle tools. They were encouraged to make the style of their creations correspond to the material employed, stressing its specific properties and limitations, and they were not allowed to overstep the bounds of its inherent potentialities. All Polish art schools possessed workshops in the most important branches of the decorative arts, such as weaving, woodcarving, metal work, ceramics, commercial graphic art, bookbinding, etc. In this way the Polish schools of arts and crafts trained their pupils to be craftsmen and artists excelling in good workmanship. According to their predilections, the graduates of these schools could either devote their talents to some handicraft, find employment as designers and skilled workers in factories, or pursue their studies in art academies.

Although in Polish art schools the mere imitation of historical styles was discouraged, yet care was taken that the pupils receive a proper theoretical education in the evolution of the fine arts through the ages, and especially, that they become thoroughly acquainted with the traditions of Polish art in all its domains: architecture, sculpture, painting, the decorative arts, as well as peasant art.

Such an education was designed for encouraging young Polish artists to fuse traditional native Polish elements with the general principles of current European art, thus facilitating them to attain the goal for which many Polish artists, both of the near and distant past, were striving. **Polish carpets.** Misleading names given to Persian carpets of the 17th cent. with purely geometrical patterns; probably came from the workshop of Kashan or Ispahan. Many of these rugs came into possession of the noble families of Poland which led scholars to believe that they were made in Poland by Persian prisoners. —B.E.J.

**polka.** Popular Bohemian dance in lively 2/4 time. **Polka-mazurka**—a slower dance in tripple time with accent on the last beat.

**polonaise.** The polonaise is said to have originated in Poland in 1573 on the occasion of Henry of Anjou's accession to the Polish throne, when the court ladies performed a stately procession in his honor. This procession later became part of court functions in Poland and elsewhere. It scarcely merits the name "dance", since it was little more than a grand march in slow 3/4 time. Sometimes, however, the simple line of march around the room was broken by dance-like figures. —J.G.

**polychromy.** The artistic combining of many colors, esp. vivid ones, as in ancient sculpture architectural decoration.

**polyglot.** *Book.* A collection in one volume of several translations of the same work.

**polygonal nimbus.** See nimbus.

**polymerized methyl methacrylate.** See acrylic resins.

**polymerized oil.** Although this term is comparatively modern, oils which could be so classed have been used from the earliest history of this material as a painting medium. They are distinguished from the common drying oils by a molecular rearrangement, smaller molecules being united to form larger molecular masses. The changes is effected by heating or, in modern commercial production, by blowing air through the thin oil. Some chemical chance occurs, also, and there is a degree of oxidation. In the older practice of painters, polymerization producing what has been called "stand oil" was brought about by heating and at times by exposure to the sun for long periods. The polymerized oil is more viscous than that which has not been treated and is apt to be more stable. —G.L.S.

**polymeter, modern.** See NOTATION.

**Polynesia, art of.** See OCEANIA ARTS OF.

**polyphony.** *Mus.* Process of composition by which two or more melodic lines are presented simultaneously, each of these lines being aesthetically meaningfull (at least to some extent) if considered separately from the other lines. This property is sometimes referred to as "independence" of the melodic lines involved in polyphony; the term **independence** should be used in this context only if it is understood that the melodic lines in question obey the principles of counterpoint, notwithstanding their self-sustained character.

Polophony also designates the music written by means of polyphonic technique; e.g., medieval polyphony: polyphonic technique used in the Middle Ages, or medieval music written in polyphonic technique. See MEDIEVAL MUSIC. —E.K.

**polyptych.** See altarpiece.

**polytonality.** Style of composition in which two or more melodic lines, or series of chords, are presented simultaneously, each of these elements being related to a different major or minor key. —E.K.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**polyvinyl resins.** These synthetic materials have had some recent use as surface films and varnishes for pictures and have been proposed also as painting mediums. They are polymerized derivatives of vinyl alcohol. The vinyl acetate is insoluable in water, is fairly flexible, colorless, and, according to tests, is stable to light. It is somewhat affected by moisture and is easily permeable. It is readily dissolved by most of the organic solvents. —G.L.S.

**pomegranate.** In Greek art, an ornament in the shape of the pomegranate fruit, circular with the characteristic projecting knob with flaring end, at the blossom end. See SYMBOLISM IN FAR EASTERN ART. —L.T.S.

**Pomo art.** See California Indian art.

**Pompeiian blue.** See Egyptian blue.

**pongee.** A fabric made from wild silk. Imitations are made of cotton or spun silk and rayon.

**Pontic ware.** See Ionian vases.

**pontil.** See GLASS AND GLASS-MAKING.

**poppy-seed oil.** Somewhat lighter in color and slower in drying than linseed oil, this has had a long use as a painting medium. It was known in classical times and was brought into rather general practice during the 17th cent. in Italy. It is still used in the preparation of some artists' oil paints. It comes from the seeds of the opium poppy, grown largely in India, Russia, France, and Asia Minor. —G.L.S.

**popular art.** See folk art.

**popular romanticism.** A term used in the criticism of painting and sculpture to describe that kind of romanticism which is concerned with the appeal of popular subject matter rather than, like genuine romanticism (e.g., Delacroix), with the invention of new visual or formal values. Typically the popular romanticist is a formal naturalist who chooses subjects which have a romantic appeal to the average man, e.g., subjects from the Middle Ages or the Near East, from Goethe, Shakespeare and other poets, literary illustration in general, popular subjects sentimentally stressing the appeal of childhood, motherhood, the home, the farm, adventure, courage, nationalism, hero worship, and the like. Representative popular romantic artists include Delaroche, Breton, Bonheur, Hunt, Millais, Orchardson, Fildes, Boecklin, Hoffmann, Cole, Melchers, Chapu, Saint-Gaudens, Dallin, and Gutson Borglum.

As a historical phenomenon, it is characteristically a 19th-cent. product, but continues in the 20th cent. in popular magazine illustrations like Saturday Evening Post, Cosmopolitan, etc., and in the work of such artists as Dale Nichols, Grant Wood, Thomas Benton, Paul Sample, et al.; and was consciously revived by Nazi Germany as a healthy, normal, native, and Nordic art suitable for the "new order". —L.D.L.

**popular song.** See song.

**porcelain.** See CERAMICS I; II.

**porcelain, artificial.** Soft porcelain: bones, gypsum, etc., used as ingredients. See CERAMICS I.

**porcellaneous stoneware.** See CERAMICS II.

**porch.** A covered structure forming an entrance to a building: outside and with a separate roof which is usually lower than the main roof.

**port de voix** (Fr.). See appogiatura.

**portable altar.** See altar.

**portamento.** A gliding transition from note to note in pitch, intensity, and timbre. Conventionally, portamento refers only to pitch but there is experimental evidence to show that the principle of a modulated transition should apply to intensity and timbre as well. —C.E.S.

**portative organ.** See MUSICAL INSTRUMENTS.

**portfolio.** Any container for loose sheets of paper is called a portfolio. One made with covered boards hinged at one side and provided with strings or tapes for tying at the other three sides is commonly listed among artists' supplies. —G.L.S.

**portico.** A covered gallery flanked on one side only by an open arcade or colonnade. Thus the term includes the exterior colonnades and *pteromae* of Greek and Roman temples, the arcaded courts of the Renaissance, and the varied cloisters of medieval times.

Porticos may be grouped into two major classifications: (a) *Trabeated.* Those using the pier and lintel or the column and lintel

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

In this type the construction is simple, involving vertical loads only. (b) *Arcuated.* Pier or column and arch. In this group the arcades are longitudinally in balance, except at the corners where care must be exercised to secure stability by buttressing or by tie rods.

In both classifications, when associated with vaulting, they must be reinforced laterally.

Very interesting examples of different arcaded treatment are to be seen in the Rue de Rivoli with simple pier and arch; the Doges Palace and Loggia de Lanze, illustrating cases where the use of tie rods is mandatory; the Colosseum and Court of Farnese Palace, showing pier buttressed by engaged columns; the Palazzo del Te in Mantua, where four grouped columns and arch afford both strength and lightness; the Cloisters of St. Paul's F. L. M., in which columns coupled transversely are varied in ever changing designs; the Basilica in Vicenza, with the Palladian motive in series; and in the Cloisters of Mont St. Michel, with staggered columns giving very curious effects in perspective.

Many charming examples of porticos in the more restricted sense of an entrance porch are to be seen in Colonial and Neo-classic houses throughout the eastern, southern and central U. S. A. Homeward, Md., Monticello, Va., and the old homes of Natchez, Miss., will serve as illustrations. See *Elements et Theorie de L'Architecture,* Guadet; *Dictionary of Architecture and Building,* Russell Sturgis, 1902; *Dictionnaire Raisonne de L'Architecture Francaise du XI au XVI Siècle,* Viollet-Le-Duc, 1867; *Encyclopedie de L'Architecture et de la Construction,* P. Planat; *History of Architectural Development,* F. M. Simpson, 1929. —L.H.

**portrait.** See ex libris.

**portrait, sculptural.** No single subject in the history of sculpture has been so popular as portraits, which have had an obvious appeal to the subject represented, to the time in which he was known, and to later periods as data of historical value. Sculptors have approached the problem of portrait sculpture in three broad ways, concentrating on a realistic likeness, a character study, or a work primarily of aesthetic value. The realistic likeness is obviously the easiest to produce, requiring merely careful study and measurement and adequate technical craftsmanship. The value of such portraits is chiefly as an historical record; as such, the great number of Roman portraits are important documents for the student of history. Greater sculptors have attempted to do more than simply record the actual human face; they have, in Rodin's phrase, plumbed the depths of their sitters and have brought to the surface what they found. Egyptian portraits, eliminating unnecessary detail and emphasizing the main lines and planes of character, are of this type; so are the portraits by Renaissance masters and by the French sculptor, Houdon, who came to understand the moods and thoughts of their subjects, then, omitting what was commonplace and accidental, amplified in stone and bronze the really significant elements. But the greatest portraitists have done more than this. They have made, regardless of the artistic value of their sitters, works of art. They have brought out the beauty of the material in which they worked: the luminous radiance of fine marble, the native character of various kinds of stone, the lovely textures of bronze and wood. They have made the surface interesting by skillful modulation, so that the light striking it is spread in a multitude of merging cross-currents. The Hellenistic Greeks and Rodin were especially successful in producing such tonal values. And, most important of all, they have constructed the planes and masses of the sculptured head in designs that, revealing the character of the subject, go further by creating objects so firmly coordinated and dynamically composed that the result is aesthetically moving. Hellenic portraiture was of this type. Among modern sculptors a master of such sculptural portraits is Charles Despiau. —W.R.A.

**posa.** Shrines or chapels in the four corners of the *atrio* of Mexican 16th cent. monasteries thus called from the pauses (*pausas*) made there in outdoor religious processions. (Occasionally also in Guatemala and Peru.) —J.Mc.

**Poseidon** (L. Neptune). Classical god of the sea, rivers and springs. His chief attribute was the trident, with which he rules the waves. In classical art he was usually represented as a stalwart standing figure, with a mature, bearded face. In later painting he was pictured by Giordano and Tiepolo, and in sculpture by Bologna, Bracci, Begas and Cecere. Often he has been the central figure of fountain groups, sometimes surrounded by Tritons and sea nymphs. —W.R.A.

**positions.** The five traditional absolute positions of the body (usually referring to the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

feet, although there are less arbitrary ones for the arms), upon which the academic classic dance is founded. These positions, based on gravity and body mechanics, were codified ca. 1670-80 by Beauchamps, first director of the Royal French Dancing Academy. (1) Heels together, toes turned completely out, so that the feet, heel to heel, are in a straight line. (2) Feet in parallel line as in first position, weight evenly distributed on both, but the heels separated by about twelve inches. (3) The heel of one foot locked parallel against the instep of the other, weight evenly distributed. (4) The forefoot twelve inches in advance of the back, but parallel, weight evenly distributed. (5) The feet locked right heel to left toe, right toe to left heel.

The five positions are the net or comb through which ballet movements continually pass, serving as anatomical and stylistic substructure to the entire academic dance.

—L.K.

**positive volume.** See SCULPTURE.

**post.** An upright piece of timber or other material used as a support.

**post-and-lintel.** A system of architecture based on vertical members suporting horizontal beams; trabeated.

**post-Colonial period.** See POST-REVOLUTIONARY ARCHITECTURE AND DECORATIVE ARTS IN THE U. S. A.

**post-impressionism.** A term used to describe French painting following impressionism, from about 1885 to 1905, in which a subjective art of self-expression succeeds objective naturalism and impressionism (q.v.). The post-impressionists were thus expressionists (q.v.) rather than impressionists. Like all expressionists they emphasized any or all of the following: the artist's conception of the expressive structure and inner meaning of objects, pattern of line, form, and color for the sake of decorative beauty, distortion for the purpose of recording subjective emotion. Post-impressionists include Cézanne, van Gogh, Gauguin Toulouse-Lautrec, Seurat, Signac, late Renoir, late Degas. The post-impressionist were succeeded by the *Fauves* about 1905, though the latter were also expressionists, who, in contrast to the post-impressionists, were more radical in departing from objective naturalism in order to express their personal emotions.

The term is seldom applied to sculpture because it developed later than painting. When used in this connection, however, it includes 20th cent. moderate-progressive sculptors such as Maillol, Despiau, and Bourdelle, and artists of countries other than France who represent an analogous stage in the development of the art, i.e., sculptors who have given up the impressionism of Rodin, but who do not represent radical expressionist distortion or cubism and abstraction. The list of such sculptors includes Kolbe, Haller, Barlach, Zorach, Manship, Milles, Scaravaglione, Dobson, Gill, Gaudier-Brzesca, Epstein, Rosandic and Mestrovic.

—L.D.L.

**POST-REVOLUTIONARY ARCHITECTURE AND DECORATIVE ARTS IN THE U. S. A.** While architecture and the decorative arts do not follow exact chronological parallels in movements from 1776 to date, it is impossible to divorce the two at any time, according to traditional background, stylistic tendencies, and aesthetic and commercial considerations. The relationship started prior to this date, but at no time reached the unity and consistency of idea achieved in the late Georgian phases in all of the former colonial states, with the advent of the influences of the Adam Brothers of England.

*1776-1790 (1800).* Reconciliation of exterior architectural details and interior architecture with furnishings, in forms, proportions and colors, became the paramount issue in the last quarter of the 18th cent. Windows became more delicate, with less prominent mullions and larger panes; the giant order was introduced and proportions of exteriors became suggestive of increased height compatable with the slender reedings and pencillings in colonettes used in interior details; rounded or oval chambers and hallways with severely refined mouldings reflected the oval backed chairs, straight slim legged furniture, and striped fabrics. Revivals of forms discovered at Pompeii and Herculaneum appeared in reliefs of urns, wreathes and garlands in the panels under the slender mantle shelves, in complete harmony with draped fabrics at windows and festoons of crystals in the chandeliers; tinted woodwork joined in the effects of rich but soft hues of the fabrics. Outstanding architect of this period was Samuel McIntire (1757-1819) of Salem; well known examples of architecture are Woodlands (c. 1788) in Philadelphia; the Nicholls House (McIntire, c. 1779) in Salem; Monticello (Thomas Jefferson, 1796) in Charlottesville, Va. Augmenting the appearance of fine living in the social centers of the late 18th

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

cent. were the great numbers of silverware objects, most of them reflecting the Adam Bros.' ovals and parabolic curves, urn shapes, and delicate engravings. The name of Paul Revere (Sr.) (1735-1818) ranks highest at this time—if not for outstanding merit in design, at least for greatest skill and popularity. American ceramics made their real beginnings at this time (excepting glass, which was generally finer in the period preceding 1776) in spite of English attempts to hold the American market with exportations of Wedgewood, Spode, Staffordshire, Minton, lustre ware, etc. After the war, British soldiers and German auxiliaries remained in America to work as skilled artisans in the ceramic fields, and the character of the wares developed by all at that time was determined by the nature of the locality. The best local wares were made in Philadelphia, the social center, whereas Vermont did not make fine pieces until mid-19th cent., due to land-title controversies.

According to some authorities, the finest decorative arts of America at this time were made in and for homes of more moderate circumstances, particularly in the Hudson Valley and Pennsylvania. The American market which had opened during the Revolutionary War for French *Toiles de Jouy,* not only brought to this country the fine wood-blocked prints in one color on white or cream linen, with popularized allegorical subjects and portrait groups of LaFayette and our own military and political leaders, but opened the way for American production of block-printed fabrics and papers. Embroidered samplers produced quieter color schemes with greens, yellows, blues and blacks, instead of the raw reds of earlier times, and stressed the above-mentioned subjects, just as modelled glass whiskey and rum bottles appeared with the portraits of Washington, Jefferson and LaFayette. Perhaps the most charming decorative arts of all were those produced by the Pennsylvania Dutch, with the largest quantity and highest artistic quality of their embroideries, decorative drawings on furniture, pottery and tin, and *Fractur* paintings falling between the years 1780 and 1830, when social conditions offered more time for leisurely or spontaneous work.

By contrast to the tremendous amount of artistic production in the eastern states, chiefly English, Dutch and German in inspiration, the Spanish contributions to the country were meagre. The Cabildo, in New Orleans (1795), was a combination of French and Spanish influences (Creole), and now houses a museum of the arts of that area at that time. In 1786 the Santa Barbara Mission was founded, of typical California Spanish style, perhaps the best in design of all the California missions built from 1769 to 1823, from San Diego to Sonoma. Most missions are now restored, and serve partially as museums. Recent researches by the American Index of Design have materially aided the student in search for the arts of the California section, prior to the settlements following the gold rushes of the mid-19th cent.

*1790-1815 (1800-1820).* When Benjamin Latrobe was a surveyor of public buildings early in the 19th cent. he deplored the country as destitute of architects or even good workmen in any branch of architectural decoration. Certainly the odds and ends of carpenter Georgian in less pretentious structures would bear out his words. However, six strong architects, among others, rose to prominence at this time, namely, Jefferson (1743-1826), Bulfinch (1763-1844), Hoban (1762-1831), Latrobe (1764-1820), Thornton (c. 1761-c. 1828), and McComb (1763- ? ). This period was transitional to that of the Greek revivals as introduced by Latrobe c. 1815, and variously has been called the **Post-Colonial Period**, the **First Federal Period**, the **First National Period**, and the **Period of the Early Republic.** The Adam phase of Georgian continued in the more pretentious domestic architecture, e.g., Homewood in Baltimore, the Shreve House in Salem, and the Dow House in Salem, but was too refined and detailed for the public buildings. The fan lights at the entrances now spanned the entire doorway; Tuscan columns, spiral stairs and new classical details made their entrance. Mansard roofs were stressed in New England; hipped roofs in the middle and southern states. Either high square three or four-storied forms were preferred for residence architecture, e.g., the President's House in Philadelphia (1792-7), or long two-storied horizontal houses with projecting bays or wings at either end, as in Homewood. Devoured were the books of Asher Benjamin, who believed that domestic styles in America should differ from the Georgian in England, and that the different materials in this country needed different handling. Stylistic foundations became increasingly classical, Jefferson among others introducing the type of Roman revivals as were expressed in France at this time, in the Virginia Capitol (1795), the University of Virginia (1818) and in the

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

National Capitol (c. 1790-1827, by Thornton, Latrobe and Bulfinch). Other outstanding architectural examples of this time are: Park Street Church, Boston (1809), New South Church, Boston (Bulfinch, 1814), the New York City Hall (Mangin and McComb, 1803), the White House (Hoban, 1792), Montpelier (Thornton, 1793), University Hall at Harvard (Bulfinch, 1813), and the Gore House at Waltham, Mass. (1800).

The fires in New Orleans in 1788 and 1794 gave great impetus to building in that area, and most authorities concede the best New Orleans architecture to have been done at the end of the 18th cent. and the beginning of the 19th cent. Simple adaptations of the more classical of French and Spanish Renaissance types were produced, embellished with graceful and delicate wrought iron gates, balconies and stairways still reflecting Creole character, and were to become unique in American traditions. The later structures in this area showed less taste and less grace and simplicity, with heavy cast iron forms of architectural decoration replacing those so charmingly conceived at the height of this style.

Interiors showed the introduction of Empire styles, with Duncan Phyfe's Adam-Sheraton phase (1795-1818) only gradually merging into a more Empire aspect (1818-1830), and with Latrobe's modifications of French Empire furniture. It was a time of mahogany veneers, carved mahogany beads, acanthus leaf and pineapple motifs, scenic wallpapers related to Revolutionary scenes, high studded rooms with white woodwork, Oriental rugs and other oriental importations, and brocade hangings. French influences in all of the decorative arts showed a domination of the ungainly Empire, completely lacking the dignity, grace or refinement of the Louis 14th, 15th, and 16th periods respectively. Duncan Phyfe (1768-1854) lightened his structures by combining 18th cent English with Empire designs, and John Goddard of Rhode Island designed solid block front furniture of admirable simplicity, but heaviness prevailed in general. Silver objects became swollen with Empire character; early 19th cent. hooked rug designs emerged from their 18th cent. sequences from purely goemetric designs to leaves, scrolls and flowers, and now added animals and birds to the foliage motifs. Simon Willard (Mass.) invented the Banjo clock in 1801, with all brass works—almost a prophesy of the industrial era about to be born, with its lamentable inability to express artistically our new-found freedom and principles, and its turn to inventions, establishment of factories, and the attempt to control decorative arts media solely by means of increasing skills and varieties of novel techniques which might result in a more profitable enterprise.

*1815-50/60. The Classic Revival.* The second National Period of architecture exhibited a completed break from the Georgian, with monuments of close resemblance to Greek and Roman temples in domestic, civic and ecclesiastical buildings. The classicism of Europe at this time had penetrated the States; cities were named "Troy", "Athens", "Ionia" and many other terms referring to classical times and places; travellers visited Greece, and Stuart and Revett's book *The Antiquities of Athens* with measured drawings, was a lure for many architects and designers. Interiors of these buildings reflected the bold simple space divisions of the Greek and Roman monuments, with heavy mouldings and friezes utilizing classical motifs, with skin rugs, and with furniture retaining the boldest of classical *décor*. The most typical monuments of the time were the Cathedral of Baltimore (Latrobe, 1821); the Bank of Pennsylvania (Latrobe, 1819) in Philadelphia; the Treasury Building, Washington (Mills, 1836); Girard College, Philadelphia (Walter, 1833); the Lee House, Arlington (1826); the Hermitage (1835) in Nashville; the residence at 107 Monument St., Baltimore (1835); and the Athenaeum, Portsmouth, N. H. (c. 1815). Strickland (1759-1823), Walter (1804-c. 1887) and Upjohn (1802-1878), all pupils of Latrobe, continued his teachings in their work. The latter years of the Classical Revival period, however, showed far less of the true Greek, and more of the French academic translations of classicism of such dull and pretentious monumentality as is to be seen in the wings of the National Capitol Building added by Walter in 1851-59). Buildings in and west of Ohio were begun c. 1820, in the style of the Greek revival and were generally well designed with only minor local differences in the more northern and southern areas until after the Civil War.

Silverware at first followed both Empire and Classic shapes and decorative motifs, later in the century to be influenced by porcelain and pottery forms. Silver-plated wares took the place of pewter after 1820. The first transfer-printed ceramic wares came into being at this time, also Rockingham semi-vitreous wares. In 1825 the first porcelain mak-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

ing in America generally attempted to follow the stylistic examples of Sevres; it was the time of the beginning of hard paste Bennington wares. The ceramics field was too busy with the establishment of factories in every locality boasting fine clay and with technical developments to show a reflection of either classical or Empire elements until the seventies, when they were more gross and lacking in taste than had they been created earlier in the century. See CERAMICS II.

Fabrics were heavy and boldly designed, following furniture tendencies in general, the best of which was Duncan Phyfe's Victorian period (1830-1847), although he was wont to call it his "butcher period" in disgust with the demands for heavy furniture. Stencilled walls continued in some cases, and printed wallpapers bore local American scenes. Heavy chandeliers carried out the preponderant weight of the *décor* of the times. Glass factories had been known to exist from the time of the 17th cent., but Deming Jarves introduced the first financially paying glass business when he incorporated in 1825, at Sandwich, Mass., following years of technical studies. A great diversity of glass types and forms of every color and usage were produced here, and while it is difficult to distinguish Sandwich glass from that of the many other houses by motif, shape or technical excellence, it has been generally admired by collectors, the most prominent being Henry Ford.

Simultaneously with the years of classical revivals in architecture and the decorative arts, a series of more romantic revivals made their appearances, not to become prevalent until the latter half of the century. Some Egyptian influences are to be seen in the Washington Monument (Mills, begun 1836), in the Old Tombs Prison, N. Y. (1836) now demolished, and in the Old Croton Reservoir, N. Y. (1837-1843) in the place now occupied by the New York Public Library. Gothic revivals joined the strong movement toward classicism in the buildings of the entire south after 1830; in the Vieux Carré, New Orleans, emblems and varied designs from the Gothic as well as from later French and Spanish prototypes appeared in heavy cast iron architectural decorations, along with invented motifs on the part of the local designers. Cast iron foundrys were started, producing balustrades, ornamental window lintels, column caps and bases, gradually more and more Gothic in character. Towers were added to white pillared houses of classic nature; in fact Gothic came into existence in every material available but that which was most characteristically used in Gothic times, namely, stone.

With Renwick (1790-1863) as the most prominent architect, some of the outstanding monuments of early Neo-Gothic are those of Grace Church, N. Y. (Renwick, 1843); St. Patrick's Church, N. Y. (Renwick, 1850); the Smithsonian Institution in Washington (Renwick, 1846-52); the State Capital at Baton Rouge, La. (c. 1847, Weiss, Dreyfous and Seiferth); and Trinity Church, N. Y. (Upjohn, 1839-46).

*Eclecticism, 1850-1893.* Known by many names (**Parvenu, Roaring Eighties, Brown Decades, Age of Romanticism,** etc.) this period roughly divides itself into the type of electicism that prevailed prior to 1876, and that which came about between the Centennial Exposition at Philadelphia in 1876, and the World's Fair or Columbian Exposition in Chicago, in 1893. For the brief time before the Civil War there was an adaptation of the Downing Cottage style of England of western Europe's smaller domestic architecture, and the above mentioned Gothic revivals. With the boom following the Civil War, and with our westward movements taking precedence over contacts with Europe, our intellectual and artistic background was not sufficient to keep up with territorial and commercial expansions. The result was a vigorous, ostentatious movement, lacking in taste, seeking its architectural and decorative arts forms in an undisciplined trail in manifestations from the most rustic to the most exotic. Diverse styles appeared, based on Swiss chalets, castellated medieval forms, jigsaw-decorated combinations of Georgian and Gothic, Renaissance (**gingerbread**) villas, Eastlake styles, Hobb's architecture (an elaboration of Downing's cottage style), Queen Anne styles (an admixture of Victorian Gothic and Eastlake), Victorian Gothic either with Italian flavor, or with Third Empire French, and Chinese, Persian and other Oriental aspects. Porte-cocheres, conical roofs, wide porches, high roofs, towers, gables, and all manner of unrelated architectural forms were jumbled together. Outstanding examples of these "brown decades" are the McCormick House, Chicago (1873); Memorial Hall at Harvard (Ware and Van Brunt); The State Capitol at Hartford, Conn. (Upjohn, 1873-78); and the Philadelphia Centennial Exposition buildings of 1876. Even in the south there was an occasional echo of a Renaissance

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

villa only in the materials available instead of the stone tile and marble of Italy, as seen at Annandale, Madison County, Miss., in 1855.

The craze for the picturesque and romantic was largely occasioned by mid-Victorian tendencies in literature, such as the writings of Sir Walter Scott, by the enthusiasms of the followers of Ruskin or Pugin, or by sudden wealth on the part of thousands throughout the country who were unprepared to announce their progress up the social ladder by other than lavish and vulgar display. Domestic interiors, like the exteriors, were of excellent workmanship, accounting for their current preservation, but of execrable taste, with panelled wainscots, golden oak beamed ceilings, profuse mill work, pictured tiles, cubby holes and mantle shelves weighted with an indiscriminate assemblage of objects ranging from Blackamoor statues and cornucopias filled with hot-house fruits, to Oriental bric-a-brac and products of taxidermy. Furnishings were eclectic, ranging from the most medievally romantic to the most heavily antiquarian with Victorian, Biedermeier and Third French Empire vogues; weighty chandeliers and lighting fixtures added to the massive conglomeration of furnitures, and the ensemble was unwholesomely lightened in appearance by billowing drapery swags and a profusion of exotic growing plants. (The Victorian furniture of black walnut and rosewood, textiles of horsehair, plush, satins and brocades, Axminster carpets of heavy floral designs predominantly red and green hues and other Victorian features have enjoyed a brief vogue in recent years due to the whims of clients who wished to dramatize their surroundings with as great a contrast to Modern as possible, or to indulge in a nostalgic escape from the pressures of a modern world).

The Industrial Revolution in England at the start of the 19th cent. had its reflections throughout the century in this country, with factory mehods, machines and inventions taking the place of the hand crafts of the preceding times. During this surge of industry was imported Victorian bric-a-brac and English and French earthenware and chinaware (one French factory simulating Limoges china having been started by an American, David Haviland, formerly an importer in N. Y.). Some locally produced ceramic forms seemed to present the lowest aspects of the artistic decline during this period. Experiments to produce novel surface effects were carried out, such as a type of marbling, slip-combing or scroddle ware; romantically conceived cow pitchers appeared, and ceramic sculptured grotesques for such purposes as ink wells, paper weights or door stops; cartoons and political jests became motifs for the ornamentation of utilitarian objects. Parallel with these tendencies were the pictorial embroidery contests, and hooked rugs bearing mottoes and expressions of sentiment.

In architecture between 1876 and 1893 there appeared a distinctly encouraging directive for the electicism to come, on the part of two Beaux-Arts trained architectural leaders, namely, Henry Hobson Richardson (1838-1886), and Richard Morris Hunt (1828-c. 1896). These men selected simpler and more direct traditional styles than had been evidenced in the borrowings prior to 1876. Richardson was mainly trained in a classical style, but worked in a Victorian Gothic manner in his first commissions. He soon turned to the strong and vital construction, picturesque masses and rich surface textures of the Romanesque of southern France and Spain, and worked so consistently in this manner for all buildings of domestic, civic and ecclesiastical nature that the movement became known as the **Neo-Romanesque.** The best examples of his work are: Trinity Church, Boston (1877); Sever Hall, Harvard (1878-80); the Field Warehouse, Chicago (1885); the Gratwick House, Buffalo (1886); and the Pittsburgh Courthouse and Jail (1884-87). Hunt was largely influenced by the French Renaissance, and was commissioned by prominent families in N. Y. to build homes simulating the larger French chateaux, as seen in the W. K. Vanderbilt residence in N. Y. (now demolished), and in the G. W. Vanderbilt residence "Biltmore", in N. Carolina. His civic structures suggested similar architectural features, e.g., the N. Y. Tribune Building (1874), and he designed the Administration Building at the Chicago World's Fair, at which time the significance of his particular contribution was absorbed in the work of fellow architects similarly trained.

During these years the character of the architectural schools in the country became fairly well established, and schools for training in the crafts began to appear, each following the stylistic tendencies of the men on the faculties. However, commercially produced art objects proved to be superior for this brief time, as in the instance of the manufacture of fine chinaware in Syracuse, N. Y., by the Onondaga Potteries, 1870 henceforth. to be followed by the Lenox plant at Trenton, N. J., in 1889.

post-revolutionary

*Eclecticism, 1893 to the Present.* All traditional styles have been utilized by architects for the past fifty years, the relative successes being governed by the good taste of the designer and the lattitude given him by the commissioner. The foremost of these stylistic selections was the Renaissance, for it had been voted to build and decorate the Exposition Buildings at the Chicago Fair of 1893 in the classical aspects of the Renaissance. Many meetings of the architects, sculptors and painters involved took place not only in Chicago but in other large cities where the offices of the designers were located, thus spreading interest and research for all possible translations of Renaissance details. Of greatest significance were the Agricultural Building (McKim, Mead and White), the Manufacture and Liberal Arts Building (Post), the Fine Arts Building (Atwood), the Horticultural Building (Jenney), and the Transportation Building by Adler and Sullivan, which was the sole departure from the stylistic manner of the Exposition. Outstanding exponents of the movement now known as the **Neo-Renaissance**, were McKim, Mead and White. C. F. McKim (1847-1909) was later the father of the American Academy of Rome, where many of our architects studied; Stanford White has been called the father of American architectural decoration. Their best known works are the Boston Public Library (1887-1895); the Old Madison Square Gardens, N. Y. (in the 90's); the old Columbia University Library, N. Y. (1895); the N. Y. Herald Building (1894); the Pennsylvania R. R. Station, N. Y. (1906-1910) and the Morgan Library, N. Y. (1906). Following the stylistic lead of these men, Carrere (1858-1911) and Hastings built the N. Y. Public Library in 1910; Chedanne added a distinctly French flavor to the Clark Mansion, N. Y.; Cass Gilbert (1859-1934) is well known for the Minnesota State Capitol Bldg. (1906), the Woolworth Building, N. Y. (1911-1913); H. Bacon (1866-1924) for the Lincoln Memorial in Washington in 1913. The other major traditional borrowing after 1893 was led by the architects C. R. Cram (1863- , B. G. Goodhue (1869-1924) and F. W. Ferguson (1861-1926), followed by Day, Klauder, and Rogers. The spirit and plan of the buildings by these men were based on medieval architecture ranging from Gothic to Byzantine, each designer progressing as far as the function of the building and his own philosophy of beauty would permit, and following the gospels of Ruskin, or the Morris and Oxford movements. The best known monuments of these men are The United States Military Academy (Cram and Goodhue, 1903); St. Thomas's in New York (Goodhue, 1906); the First Baptist Church, Pittsburgh (Cram and Goodhue, 1909); St. Bartholomews in N. Y. (Goodhue, 1914); St. John's the Divine, N. Y. (LaFarge and Cram); the San Diego Exposition Building (Goodhue, 1915); and the Capitol Building in Lincoln, Nebraska (Goodhue, 1925). (These men were frequently called to collaborate with local architects in other parts of the country, e.g., Cram's part in the planning of the Doheny Memorial Library, University of Southern California (1931); Goodhue's Los Angeles Public Library (1925) belongs rather to the modern style into which his earlier designs merged.) Other outstanding monuments in this tradition are the Museum of the University of Pennsylvania (Day, Cope, Stewardson and Eyre); the Princeton dormitories (Day and Klauder); the Harkness Memorial Tower at Yale (Rogers); and the Cathedral of Learning (University of Pittsburgh) (Klauder).

The first skyscrapers were Romanesque in appearance, their home being in Chicago where the first architects to attack their problems were located. Skyscraper projects had been under way since 1880, dependent on inventions in metals and glass, in the fire-proofing of metal materials, and in the varied inventions of elevators. The Tacoma Building in Chicago (1887-1888) by Holabird and Roche was the first building to have the outer walls entirely supported by the interior metal skeleton; Jenney's Leiter Building in Chicago (1889-1890) was the first building in which all the walls were supported internally. Burnham and Root were occupied with further solutions, to be followed by Adler and Sullivan, in whose hands the buildings grew out of the Romanesque into their more recent Rationalistic trend. New York skyscrapers stressed the Renaissance details affected by their designers in general as seen in the New York City Administration building by McKim, Mead, and White (1908) and the Woolworth Building (1911) by Gilbert. The trend toward greater verticality stimulated Gothic details as seen in the prize-winning design by J. M. Howells and R. M. Hood in the Tribune Building Competition in Chicago (1922). Since that time the aesthetic and structural story of the skyscraper belongs mainly to the movement which has been termed **Rationalistic**, due largely to the design submitted by Eliel

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Saarinen in the 1922 competition, and his successors.

The movements in decorative arts showed the influence of expositions since 1876. The pendulum swung between the extremely practical aspects at the Philadelphia Centennial, to the "art for art's sake" appearances in the World's Fair in Chicago, back to a union of arts and crafts at the St. Louis Exposition of 1904, to the practical arts at the fairs in San Diego and San Francisco in 1915, and back to the extremely decorative at the Exposition of Decorative Arts in Paris in 1925 which had such a wide-spread influence on subsequent designs. In 1881 William Morris in England started the "Honest Crafts Movement" in revolt to the poverty of design brought about by machine-made objects in the 19th cent., and stimulated his artists to turn to medieval examples of decorative arts for their inspiration in returning to hand craftsmanship. During the 1888 Arts and Crafts Exhibition in London, a society was formed which was parent to most American crafts organizations of the present century. *L'Art Nouveau* of Belgium and France at the end of the 19th cent. did not enter America's trends in design except briefly at the time of the St. Louis Exposition. The china-painting vogue climaxed at this time; so-called "art groups" of ceramic sculptures appeared, utilizing white parian wares, and not only continuing a type of mid-Victorian sentimentality, but creating an American *genre* with such well known sculptors as John Rogers and Daniel Chester French participating. For utilitarian wares, an epidemic of "jug towns" came about. Tapestry manufactories such as those of Baumgarten and of Herter were started in N. Y. in the early 20th cent., the designs ranging through all subjects from the medieval times to the present, consistent with the preferences for furniture of Florentine, Roman and Venetian Renaissance, and of all French styles of furniture of the 18th cent.

In the making of hand-forged and hand-carved iron doors, gates, grills, and other ornamental features of architecture, Samuel Yellin of Philadelphia (1886- ) has achieved outstanding fame, and examples of his works are to be seen in many museums. Designers of architectural decoration stressed a style maturing about 1910 which appeared to be a combination of the ornaments of any or many historical periods, the motifs seeming to be selected from transitional times where there were no fixed forms. Contemporary with this group was another movement on the part of men who recognized that ornament should not be the determining agent of the style of architecture. They ignored books on historic ornament and sought a study of masses, proportions, and textures destined to bring out the technical beauties of the engineering of a monument. The principles of this latter group were incorporated by the larger number of industrial designers who recommended the machine as an art tool and who were only temporarily swerved from their course by the designs introduced at the Paris Exposition of Decorative Arts. Immediately following this exposition of 1925 a brief period of "modernistic" filled the *ateliers* of designers and department stores in large cities (cf. pictured examples in Park, *New Backgrounds for a New Age*) to be dissolved in the more contemporary manner of architects and designers in a greater harmony of so-called "rationalistic" forms.

*Rationalism in America, 1890 to the Present.* The utterance of Louis A. Sullivan (1856-1924) to the effect that "form follows function" gave the first name of **Functionalism** to this movement in architecture as a social expression and with complete interdependence of form, function, and decoration. His transportation Building at the World's Fair in Chicago (1893) showed a marked departure from the Romanesque traditions seen in his earlier work as typified by the Auditorium building in Chicago (1886-1889). In his contributions to a more organic type of office building and in his residences of the late 19th and earlier 20th cent. in the midwest are to be seen the simple character and texture-stressing ornament that has been carried on by his outstanding pupil, Frank Lloyd Wright (1869- ). The dynamic experimentations of Mr. Wright certainly establish him as America's foremost modernist, esp. in residence design, and his writings have perhaps stimulated more thought and controversy than any other. From the time of his early works in 1894 he has consistently stressed horizontality; he has indicated his worship of the machine as shown in his use of pre-cast concrete blocks and geometric motifs, and has desired to reduce all building design to the simplest possible terms, in cooperation and harmony with the natural surroundings. His predilection for projecting eaves and cantilevered units has been well known since his successful use of them in the Imperial Hotel of Tokyo which withstood the severe quakes in 1923. The early difficulties of Wright in harmonizing exterior

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

and interior architecture with the furnishings owned by people or produced by furniture factories in general, and which he attempted to solve by actually creating furniture, lighting fixtures, and other decorative arts, are no longer major problems. Modern furniture designers such as Paul T. Frankl, Kem Weber, Donald Deskey, Gilbert Rhode, Joseph Urban (1872-1933, also a stage designer of great note) and others have produced furnishings of all categories which are compatable with the new materials and principles of modern architectural design. Among modern architects of more monumental edifices Raymond M. Hood (1881-1934), Eliel Saarinen of Finland (now at Cranbrook) and Ely J. Kahn (1884- ) rank high. The influences on America by the Bauhaus, started in Germany early in the 20th cent., and by many of its leaders who are now in this country, are yet too indirect and too contemporary to be seen in any perspective.

The word "functionalism" is not recent in connection with the decorative arts either, for since the first of the 20th cent. arts and crafts societies have used this word to describe their designs. The modern designer, particularly since 1925, has been interested in developing an object which appears decorative in the home through fine handling of material, shape, color and texture, but which does not depend individually upon ornamentation for its decorative effects. The industrial designer of today, exemplified by the above mentioned men, and by Norman Bel Geddes, Russel Wright and Raymond Loewy among others, must not only know his art, but the machines which are to translate the designs to the finished product. Considerable variance in the interpretation of Modern has resulted in designs ranging from elegance and sumptuousness suggestive of traditional periods (especially the American Indian, Persian and far-Eastern *décor* stressed in recent exhibitions), or of modern painting to the craft viewpoint where designs of simple effectiveness are produced either by a direct shaping of materials with the hope that good design will automatically result or by working out patterns to be translated by simple tools, e.g., the loom, rather than the commercial machine. Neither is as yet completely capable of mass production any more than is the continued creation of traditional styles in all of the decorative arts, especially in furniture. Since merchandisers have stimulated not only seasonal changes but regional styles, the great variety of so-called "Rational" forms, patterns and surface textures range from the most naïve to the most formal or effusive.

Outstanding names of the present day in the making of glass are Dorothy Thorpe of Los Angeles and the designers of the world famous Steuben glass made at the factory at Corning, N. Y.; for modern textiles—Dorothy Liebes of San Francisco, Ruth Reeves and Marguerita Mergentime of N. Y.; for modern ceramics one turns to the repeat prize winners of the annual shows of the National Ceramics Exhibition, first established as the Robineau Memorial Exhibition, of Syracuse, N. Y., in 1932. For pottery, the names of Arthur E. Baggs, Cleveland, Glen Lukens, Los Angeles, Edgar Littlefield, Ohio, and Henry Varnum Poor, N. Y., appear most frequently; for ceramic sculpture those of Waylande Gregory, Michigan, Paul Bogatay, Ohio, Russell B. Aitken, Cleveland and Victor Schreckengost, Cleveland. Special prizes were given to Edward Winter of Cleveland in the field of enamels. Most handwrought silver has been made by individual designers within large organizations, but in recent years museums such as the Cleveland Museum of Art have sponsored competitions for the independent silversmith. Hudson, B. Roysher, Los Angeles, has won many awards in such competitions. Work such as submitted by these silver craftsmen and by other designers in precious materials, demanding precision of skill and long hours of thoughtful care in handling, will no doubt serve as guide posts of sound craftsmanship and sure knowledge of good design for those who work with new synthetic or relatively inexpensive materials, or who follow an undisciplined concept of Modern as a "growing style".

Outstanding collections of American decorative arts are to be seen at the Art Institute of Chicago, the Metropolitan Museum of Art, N. Y., the Brooklyn Museum of Art, the Pennsylvania Museum of Art, the Cleveland Museum of Art, the Museum of Fine Arts, Boston, the Detroit Institute of Arts, the William Rockhill Nelson Gallery of Art in Kansas City, and the M. H. de Young Memorial Museum in San Francisco. See EARLY AMERICAN ART; also Avery, C. Louise, *Early American Silver*, 1930; Edgell, G. **POST-REVOLUTIONARY PAINTING AND SCULPTURE IN THE U. S. A.** The chronological divisions below are arbitrary, for painters and sculptors elude the more exact classification that was possible in the development of architecture and the decorative arts. The type of patronage was different, and while their works were as generally reflective of the society in which they were created, each man is an individual problem. The sources of his training were usually multiple and the man may have changed the nature of his work many times as he grew older or met influences strong enough to alter his viewpoint or manner of presentation, thus lifting him from one category into another.

Scholars have found the matter of classification of painters and sculptors since 1776 like that of handling quicksilver; for instance, Homer St. Gauden's (1941) began by tying he men who worked after the Revolution-ry War to those who preceded it by some years in all-inclusive group dated 1750-1828, the latter date being the year of the death of Gilbert Stuart. He followed these by a unit ending in 1876; for him there seemed to be a distinct group between the Fairs of 1876 and 1893, after which are the Contemporary men. Virgil Barker (1931) has generally followed Samuel Isham in the first of his categories, namely, the "Colonial", ending c. 1790, the "Provincial" ending in 1876 and the "Cosmopolitan" to the time of the Armory Show in New York in 1913. His last group he approached qualitatively, calling them "Contemporary", and attempting to sub-divide by style, as an aid for further study and possible reclassification. Alfred Barr in his catalogue of the American Exhibition in Paris under the auspices of the Museum of Modern Art, 1938, divided his survey arbitrarily into painting since 1776 to the time of the Civil War, thence to the year 1900, and then simply "Twentieth Century American Painting". Another 1938 exhibition of Contemporary American Painting, in London, was accompanied by a catalogue with an introduction by Henry McBride, who suggested that American painting development had followed a chronological swing of the pendulum first from the British influences, to the native tendencies exhibited in the Hudson River School, then back to influences from abroad, and finally back to America with the Contemporary men. Suzanne La Follette (1929) allowed her colonial painters to extend to 1800, after which she found two main groups, placed under the headings of "Material Expansion and Artistic Contraction", 1800-1876, and "Recommencements" after 1876. For Mellquist (1942), all painters before 1898 were the "Forerunners", to be followed by a series of men in "Revolt" until World War I; thereafter for him the men were the "Culmination".

Lorado Taft attempted even more difficult organization in the field of sculpture, there being little of importance prior to 1850, and not many more artists of relatively outstanding merit in the intermediary period to 1876. With him, as with other writers, the last division of "Contemporary" referred to the inclusive time of the types of works which are still produced today. His death prevented a newer edition of his important history of American sculpture to include men of the last two decades, and anyone seeking names of current prominence in the field of sculpture, as in painting, must go with trepidation to as unbiased and objective sources as possible, with full knowledge that some names a generation hence may prove to have been of transient worth, whereas others at this time modestly observed, may rise to greater favor with the light of perspective thrown upon them. Work such as is currently undertaken by the American Art Research Council and by other centers of similar investigation will prove to be of inestimable value in the future.

The categories here selected are simply those of fifty-year intervals, there being sufficient evidence of traditional and stylistic preferences within each to make the classifications possible when based on training, technique and style rather than on content or concept. Since 1776 there have been "revolts" in every period as to subject matter and the personal idiom; subjects which today would be called "Regional", "Provincial" or the "American Scene" abounded in the 19th cent. in *genre* paintings, in so-called "Primitives", or in Currier and Ives prints. To date, if viewed objectively, there have been no "Culminations" as such in the crucible of progress-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

sive movements. As has been seen, a distortion of time or tendency is bound to result when a particular thesis is expounded. Therefore, no thesis is here presented, and the developmental progress in the crafts of painting and sculpture seems to be the more logical to tie to for some type of chronology, at least until the 20th cent., since biographical material herein is out of the question. Names brought forth are those which, to 1943, have been most universally accepted by scholars and critics, and in terms of museum purchases and representation in collections of reliable dealers and recognized patrons.

*The First Fifty Years, 1776-1826.* This period is marked by a strong adherence to the style of social paintings in England, due mainly to patronage, to familiarity with the techniques evolved prior to the Revolutionary War, and to the fact that territorial expansion until after the first quarter of the 19th cent. was not sufficient to tempt the painter's eye away from the strong cultural contact of England. After 1763, when Benjamin West (1738-1820) settled permanently in London, a large group of American painters studied with him at his school. Among them were the following men of note: Matthew Pratt (1734-1805), Charles Willson Peale (1741-1827), his son Rembrandt Peale (1778-1860), Abraham Delanoy, Jr. (c. 1740-c. 1790), Henry Benbridge (1744-1812), Edward Savage (1761-1817), Joseph Wright (1756-1792), William Dunlap (1766-1839), John Trumbull (1756-1843), Robert Fulton (1765-1815), E. G. Malbone (1777-1807), Henry Sargent (1770-1845), Thomas Sully (1783-1872), Samuel Waldo (1783-1861), Washington Allston (1779-1843), Samuel F. B. Morse (1791-1872), possibly Ralph Earl (1751-1801) who visited him and at least had his advice, and Gilbert Stuart (1755-1828). Thus while the type of painting which had been styled "Colonial" was the tradition during the early years of West's life and was based generally on Lely and Kneller, these later man reflected West's more sophisticated manner and that of Reynolds, Romney, Lawrence and Hoppner, some of the above men studying for some time with the English masters. Several continued English portrait tradition well along into the 19th cent., such as the popular Sully. Even a group of independent portrait painters uninfluenced by study abroad, such as Chester Harding (1792-1866), John Neagle (1796-1865), J. Eichholtz (1776-1842), and J. W. Jarvis (1780-c.1835), would pose their subjects similarly to the English-trained group, with the same background foils of turbulent skies or monumental architecture, although more realistically direct and less sophisticated in manner.

Miniature painting did not come into its own in America until after the Revolutionary War, and faded into obscurity some sixty years later with the introduction of photography. Malbone, Fulton, James Peale (1749-1831), Robert Field (c. 1765-1819), Walter Robertson (1765-1802), Benjamin Trott (c. 1770-1841), Charles Fraser (1782-1860), and Raphaelle Peale (1774-1825), also a painter of still-life, are among the most notable. John Ramage painted miniatures in this country from 1774-1794, among them one of George Washington; Charles St. Memmin who came to this country from France in 1796, perhaps painted the most reliable miniatures of Washington, due to his reputation as a physiognomist.

The three items of greatest single interest occurring in the latter part of the 18th cent. have probably been the paintings made of George Washington, the paintings made by Gilbert Stuart, and the paintings by Ralph Earl. Controversies over authentic portraits of Washington (1732-1799) have waxed hot. We know that C. W. Peale painted him in the uniform of a colonel in the Virginia Militia in 1772; he painted another in 1795; Robert Edge Pine came to this country in 1784 and lived here until his death in 1788, painting Washington in 1785. Edward Savage painted a portrait of the Washington family in 1789 and finished it in 1796, as well as one of Washington in uniform in 1790 and another in civiliar dress. Christian Gullager (1762-1826/7) painted him in 1789. However, Gilbert Stuart's portraits are the most famous, since he not only painted Washington many times from life, but copied his paintings for ardent patrons over many years following. His so-called "Vaughan" portrait of 1795, now in the National Gallery in Washington, reveals the right side of Washington's face; the left side is shown in the full-length picture called the "Lansdowne" portrait of 1796 and in the "Athenaeum" portrait c. 1795, of which he made many copies.

Not only because of these portraits, but because of his superb handling of paint, Gilbert Stuart deserves special attention. He painted well even as a young boy, and after his return to New York in 1793 following several trips abroad, hundreds of portraits have been attributed to his swift and competent hand. His pearly flesh tones were his

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

greatest contribution; the rest of the figure he handled with great economy of paint and effort, if at all, since his prime interest was the study of character.

The paintings of Ralph Earl, who has been listed indiscriminately under headings of sophisticated paintings, provincial paintings, and even of folk arts, are enjoying a new recognition because of our present day search for things typically American. As early as 1775 he painted a view of the town of Concord, Mass., believed to be the first historical painting by an American artist. He was an itinerant painter, but revealed a refreshingly "native" character in his paintings of the last quarter of the 18th cent., with strong design, good color, and fine pictorial sense.

Of sculpture in the first fifty years following the Revolution, there is little to say. Patience Wright, mother of the above-mentioned painter, went to London in 1772, where her modelled figures in wax became internationally famous. Other than the portraits of George Washington by the French sculptor Houdon in 1785-1788, the American yields boil down to the wood-carvings of William Rush (1756-1833) and of Hezekiah Augur (1791-1858). The stone carvings of John Frazee (1790-1852) moved into the next chronological period, with frankness and expressiveness half way between folk art and classicism. Otherwise folk arts such as polychromed ships' figureheads, cigar-store Indians, small wood sculptures of animals, birds and men, lawn figures, gravestones, weathervanes and cast-iron stoveplates, made up the larger number of plastic arts contributions, and have become increasingly important as reflectors of the social-economic aspects of the times.

Transitional to the next chronological period of painting were examples of folk arts in the craft of painting on velvet, silk, canvas and glass, exhibiting in spite of an abstract character and untutored manner the predilection for portraits, miniatures and family groups in the late 18th and early 19th cent. that marked the work of the professional painters after 1826, and for the landscapes, *genre* subjects and historical scenes which were the outstanding constributions of the men to be cited in the group dated 1826-1876. Transitional to the professional class of painters one finds listed the names of Washington Allston and John Vanderlyn (1776-1852), who went to Paris to study. The romantic leanings of these two led into a movement in painting which stressed landscape instead of figures, namely, the **Hudson River School.** William Dunlap, famous for his volumes entitled *The History of the Rise and Progress of the Arts of Design in the United States,* published in 1834, and John Trumbull contributed to the tendency towards historical scenes. The founding of the art school of the National Academy of Design (now the National Academy) in 1826 marked the end of a craft primarily taught in England, and inaugurated an era of training in America and on the continent.

*1826-1876.* Neo-classicism in sculpture resulting directly or indirectly from study in Italy with Canova or Thorwaldsen is to be seen in the works of Horatio Greenough (1805-1852), Hiram Powers (1805-1873), Thomas Crawford (1813-1857), Erastus D. Palmer (1817-1904), William Wetmore Story (1819-1895), Harriet Hosmer (1830-1908), Randolph Rogers (1825-1892), and William H. Rinehart (1825-1874), the founder of a scholarship fund for study abroad in sculpture. Little or no evidence of this type of pseudo-classicism based on linear and decorative compositions appeared in the works of painters. The only marked parallels in painting and sculpture were primarily the more native elements such as can be observed in the plastic works of Joel Hart of Kentucky (1810-1877), Henry Kirk Brown (1814-1886), Clark Mills (1815-1883), and the *genre* groups of John Rogers (1829-1904), and secondarily in the academically trained sculptors who went to Paris instead of to Rome in the 60's and 70's. Two outstanding men served to bridge the gap to the type of sculpture continuing through to the present day, namely, John Quincy Adams Ward (1830-1910) and Olin Levi Warner (1844-1896).

Painting took two directions during the period of 1826-1876, one a continuation of figure painting, and the other, that of landscape painting. Each presented what might be called a native (provincial) character on the one hand, and a continental aspect on the other. Figure and portrait painters who moved westward in the country were likely to reflect their new environmental conditions in a type of American *genre,* to be found in the works of George Caleb Bingham (1811-1879), David C. Blythe (1815-1865), William S. Mount (1807-1868), Richard Caton Woodville (1825-1856) and others. Those who went to Europe to study, or remained in the east to work with American masters reflected the influences from abroad more directly. These men were Emanuel Leutze (1816-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

1891), Eastman Johnson (1824-1906), George Fuller (1822-1884), Charles Robert Leslie (1794-1859), William Morris Hunt (1824-1879), J. G. Brown (1831-1913), Alvan Fisher (1792-1863), and the muralists John La Farge (1835-1910), Elihu Vedder (1836-1923) and Charles Caryl Coleman (1840-1928). European influences at this time were the traditions of Hogarth and of the Dutch *genre* masters, the academies in Munich and Düsseldorf, the poetry of the Barbizon painters of France, the academic portrait and figure painters of France, and the murals of Puvis de Chavannes.

Halfway between these men and the landscapists were the works of groups of men ranging from the naturalist John James Audubon (c. 1785-1851), the whimsical John Quidor (1801-1881) and th artists of Currier and Ives lithographs (important between 1835 and 1889, at which latter date the first true chromolithography appeared in America), to the so-called "primitive" painters who combined figures and landscapes in their self-taught and semi-abstract fashion. Hundreds of names of painters of this latter category have risen from former anonymity, chiefly those of Edward Hicks (1780-1849), J. S. Ellsworth (1811-c. 1873), Eunice Pinney (1770-1849), J. W. Stock (1815-1855), Joseph H. Headley who worked c. 1840-60, and Rufus Porter (1792-1884) and Joseph Pickett (1848-1918) whose work carried on into the subsequent period.

The movement toward landscape painting has been styled the **Hudson River School**, because of its early concentration in that area. The romantic and poetic landscapes coming from the brushes of Thomas Doughty (1793-1856), Thomas Cole (1801-1848), Asher B. Durand (1796-1886), and John W. Casilear (1811-1893) were largely Italian in tradition, the exactitude of details, the formal compositions and the color formulas coming from Titian through Rubens and Claude Lorrain, who had gone to Italy to study. Attempts to secure unlimited space, and effects of air and light were to a large degree frustrated by the current demands for faithfulness and precision of representation of all things within the range of the artist's eye. The later works of Doughty and Durand bore evidences of the style of Constable, and the influences of the more atmospheric Barbizon school. J. F. Kensett's (1818-1872) works reveal marked leaning on Constable; Albert Bierstadt (1830-1902) showed that his Düsseldorf study with Lessing had made an indelible impression on him even in his more dramatic paintings of Yosemite Valley and in California, during far-west migrations in the mid-18th cent. The lyrical romance of Düsseldorf styles made intimate and sentimental by devoted care in drawing and painstaking brushwork, was in marked contract to the grandiose, sensational and sweepingly broad techniques taught at the Munich academy; few landscapists sought Munich until after 1876.

*1876-1926.* This period might be styled that of technical experiment for the first thirty years, and after that of experiments in interpretation as well. The two groups of the previous period began to blend by introducing landscapes as more frequent backgrounds for figure groups, or interpreting figures in out-of-doors light rather than in the constant light of the studio. First to move out of the characteristics of painting prior to 1876 were the landscapists George Inness (1825-1894) who started with Hudson River School precision, moved on to Barbizon School atmosphere, and eventually to tonalism where he began to see his compositions as emotional units; F. E. Church (1826-1900), a pupil of Cole; Thomas Moran (1837-1926), W. Whittredge (1820-1910), William Keith (1839-1911), Alexander Wyant (1836-1892) and Homer D. Martin (1836-1897). The Barbizon character of Inness, Wyant and Martin, where moods took the place of literal representations of nature, was half way between map-like photographic aspects, and the emotional qualities of light. Inness was one of the first to mix white pigment with color; from here on the problem of overcoming technical limitations in order to paint sunlight, was paramount. It was first attacked by the use of thick white paint, thus forcing light by contrast; since this lacked the life of real sunlight, small brushstrokes of broken color came next, to produce vibration. As the width and length of the brush stroke made a big difference in the quality of vibration, Frank Duveneck (1848-1919) tried the broad Munich-type strokes to effect his luminosity. Various experiments called **Tonalism** were made by a group including Inness, Keith, Albert P. Ryder (1847-1917), J. Francis Murphy (1853-1921), Henry W. Ranger (1858-1916), and Ralph A. Blakelock (1847-1899). Ranger, for example, painted his canvas entirely with white, and let it dry. Then a thin coat of golden color, or the prevailing hue of the picture, was painted over it, and the subjects painted into that hue with all the other col-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

ors. Another coat of the basic hue was then added, and subsequently a repetition of the former process, making many thin layers of color. The chief color selections of these men were raw umber, burnt sienna, raw sienna, burnt umber and yellow ochre, with the pervading hue established by underpainting with the tonal color, and at times painting the subjects into this before it was dry. Inness' method of painting the glow of the setting sun by putting a thin transparent coat of red over a dry coat of white was followed by similar attempts to secure the richness of transmitted color. A group of men who moved from these experiments to the adaptation of the high keyed colors of Monet, and pure colors placed side by side for mixing by the eye of the spectator, have been called **Luminists.** Outstanding among them were Charles H. Davis (1856-1933), Willard L. Metcalf (1858-1925), and Childe Hassam (1859-1935) whose works of opalescent beauty have also been cited under the heading of Impressionism.

The men who have been classified as "Impressionists" were primarily landscape painters who at times also used techniques other than those precisely impressionistic, and who modified the facts of the landscape to secure the mood of the setting. Rather than an exact translation of French impressionism and its subsequent movements toward pointillism, etc., the American painters depended on their own observations and experiments, as in the case of Emil Carlsen (1853-1932) who put on paint, scraped it off, put more on, with each coat thin and dry, and thus built up his composition of tumbling water and old trees with sunlight striking them. Abbott H. Thayer (1849-1921) was one of those men whose study of the physical properties of color led to the knowledge of protective coloration, or camouflage. Ben Foster (1852-1926) and Dwight Tryon (1849-1925) presented pastoral scenes showing poetic early morning, sunset or moonlight effects. Later Impressionists, as Robert Reid (1862-1929), Frank W. Benson (1862- ), F. C. Frieseke (1874-1939), Robert Spencer (1879-1931), Edmund C. Tarbell (1862-1938), Daniel Garber (1880- ), Ernest Lawson (1873-1939), J. W. Twachtman (1853-1902) and Maurice Prendergast (1859-1924) each presented sunlight in his own way, although unmistakably following Impressionist dictates of fleck-like strokes with no distinct outlines of forms, informal picturesqueness, no particular organization of design, and primarily pleasurable aspects of nature.

Contemporary with Impressionists and Luminists were a group of landscape painters who were impatient with vague contours, and who tried to infuse a new solidity into the forms of their subjects. Their modelling of shapes of clouds, rocks, trees and water by means of bold brush strokes, brought to them such names as **The School of Direct Painting,** the **Athletic School,** or the **Sculpturesque Painters,** by their friends and critics. It was the indirect result of Munich training, most likely instigated by Edward W. Redfield (1869- ) and carried on by Gardner Symons (1863-1930), William Wendt (1865- ), W. Elmer Schofield (1867- ), Jonas Lie (1880-1940), Paul Dougherty (1877- ), and Birge Harrison (1854-1929), among others.

The three Americans who have been most revered for their independently American styles in a period characterized by academies, obvious technical explorations, or revolts, are Thomas Eakins, Albert P. Ryder, and Winslow Homer. One places Eakins (1844-1916), with his accuracy of observation, among the objective *genre* painters, and Ryder among the tonalists, where he painted the creations of his imagination. Winslow Homer (1836-1910), evades classification. Self-trained, and with keen powers of observation, he became an excellent draughtman, and whether he painted the sea or anecdotal subjects in oil or water color, he infused such dramatic realism, vigor, freshness or grandeur, that the stylistic experimenters appeared tedious by contrast.

The figure painters in the period of 1876-1926 continued to a degree the *genre* types of the previous years, as seen in the works of Thomas Hovenden (1840-1895), William Harnett (1848-1892) and the important Thomas Eakins, but after the World's Fair in Chicago in 1893, the tendencies of the academies of France prevailed in easel and mural painting, and in work of illustrators. F. D. Millet (1846-1912), Edwin A. Abbey (1852-1911), Kenyon Cox (1856-1919), John W. Alexander (1856-1915), Julian A. Weir (1852-1919), A. B. Frost (1851-1928), George de F. Brush (1855-1941), and Thomas Dewing (1851-1938), for example, ilustrated the thorough training in drawing and design, the strong sense of form, the acquaintance with anatomy, and, in general, the dignity of subject that characterized the French academies. Similar were the results of training in the Royal Academy at Munich, only with emphasis on the handling of pigments, as seen

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

in the works of Frank Duveneck and William Chase (1849-1816). John Singer Sargent (1856-1925), trained in the academies on the continent and in London, always maintained the freshness of his personal expression in spite of an aristocratic patronage and large numbers of commissions: J. A. McN. Whistler (1834-1903) retained his personal sensitivity and subtlety in spite of a lifetime in London and Paris, both in his paintings and in his etchings. His temperament and his interest in the arts of the Far East, which became such a vogue late in the 19th cent., produced the combination of whimsical fancy and of simplicity, the latter being the particular result of his study of the tonal qualities of Japanese prints. Mary Cassatt (1845-1926) and Cecilia Beaux (c. 1863-1942) will never be forgotten for their fine draughtsmanship and color, unusual at that time for women, and above all for their helpfulness to American painters in Paris and their stimulation of art patronage.

A timid impressionism among figure painters started with Theodore Robinson (1852-1896), and moved primarily into the field of landscape with the above mentioned Impressionists and with such painters as Lillian Genth (1876- ) who was wont to paint nudes in wooded settings, or secondarily into figural groups wherein the interpretation suggests the most poignant moment, fleeting mood or essence of the subject for translation, such as are to be seen in the paintings of frontier life or of Indians, by Irving Couse (1866-1936), William Leigh (1866- ), Brush, and the illustrator Frederick Remington (1861-1909). Once the style of Impressionism had become established, some of its men who were superb draughtsmen and colorists became academicists in a new meaning—that of conservatism (as opposed to the revolts taking place since the formation of **The Ten**) with Gari Melchers (1860-1932), F. J. Waugh (1861-1940), Charles Hawthorne (1872-1930) and Frieseke being outstanding among them.

Rivalry came about as early as the 1880's between the National Academy, and the Society of American Artists which had sprung into existence mainly through the efforts of such men as Dewing, La Farge, Cox, Brush and Thayer due to the extreme conservatism of the Academy. They came to a common agreement in 1906 however, after the activities of **The Ten**, formed in 1898, in which Dewing, Twachtman, Tarbell, J. A. Weir, Metcalf, Hassam, Reid, Benson, J. R. De Camp (1858-1923) and E. E. Simmons (1852-1931) proclaimed their interest in individual experiments to clear their palettes, and in more progressive ideas, rather than continuing the traditions of the Academy. A series of revolts henceforth was inevitable, for painting was not yet expressing typical qualities of contemporary everyday American life. In 1908 the so-called **Ash Can School** or **The Eight** was founded, with Arthur B. Davies (1862-1928), George Luks (1867-1933), Everett Shinn (1876- ), John Sloan (1871- ), Robert Henri (1865-1929), William J. Glackens (1870-1938), M. Prendergast and E. Lawson, who portrayed realism with rich observation of emotions, humble life and picturesque types, and starting the 20th cent. movements in what has been called "regionalism" and the "American scene". In 1905 and for many years hence, another company of artists met at Alfred Stieglitz's small galleries at 291 Fifth Avenue, N. Y. At the increasingly famous "291" they exhibited photographs, experiments in which induced a new aesthetic, then etchings and prints, and finally paintings by men who were wildly enthusiastic about the Post-Impressionist manifestations in Europe. Seven men of "The Eight" were members of an Association of Painters and Sculptors which brought about an international exhibition of painting and sculpture at the Armory of the 69th Regiment, N. Y., in 1913. The **Armory Show** displayed to an unprepared American eye the 19th and early 20th cent. evolutions of European "isms" in all stages from the neo-classicism of Ingres and romanticism of Delacroix, through the structures of Cezanne to the cubistic organizations of Duchamp and Picasso, and the color and space organizations of Matisse and the "Fauves" as well as other tendencies not only by European masters but the American artists who followed them. Two Americans who lived in Paris at this time, S. MacDonald-Wright (1890- ) and Morgan Russell (1886- ), created one of the "isms" of Post-Impressionism, which they called **Synchromism.** They returned to this country and helped bring about the Forum Exhibition of Modern American Painters in N. Y. in 1916, where works by themselves and fourteen others were selected from fifty applicants to display the "new aesthetics". Ben Benn (1884- ), Thomas H. Benton (1889- ), Oscar Bluemner (1868-1938), Andrew Dasburg (1887- ), Arthur Dove (1880- ), Marsden Hartley (1877- ), John Marin (1870- ), Alfred Maurer (1868-1932), Henry L. Mc-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Fee (1886- ), George F. Of (1876- ), Man Ray (1890- ), Charles Sheeler (1883- ), A. Walkowitz (1880- ), William Zorach (1887- ), Morgan and Wright composed the group. Each in his own way sought a spatial organization of rhythmic lines, colors and masses abstractly achieved to suggest forms of non-objective character to the observer in the hope that his emotional response would be akin to that stimulated by music, and in many ways similar to the effects produced later by Wilfred's color organ (q.v.). These assertions of volumes composed of color and light revealed qualities of oriental sensuousness now seen as one of the indirect results of stimuli given to painting by the Mohammedan exhibitions in Europe in 1904 and 1911, and other exhibitions of exotic art, and by the study of oriental philosophies. Art movements started by these men and all revolts of one kind or another against the Academies of Europe and America, were to become in themselves kinds of Academies wherein there were varied approaches once again to the fundamental principles of form and draughtsmanship with the eventuation of more realistic representations. Several of this group have handed down through teaching and contact with other present-day painters the lessons of such dynamic experiences, where experiment in techniques, idea and interpretation became one.

Transitional to the Contemporary period, which herein has been arbitrarily dated 1926-1943, were the abstractionists Preston Dickinson (1891-1930), Allen Tucker (1866-1939), Stuart Davis (1894- ), and Lyonel Feininger (1871- ), and such significant realists as George Bellows (1882-1925), Leon Kroll (1884- ), Gifford Beal (1879- ), Eugene Speicher (1883- ), Edward Hopper (1882- ), Victor Higgins (1884- ), Maynard Dixon (1875- ), E. L. Blumenschein (1874- ), Walter Ufer (1876-1936), Guy Pene du Bois (1884- ), John Sloan (1871- ), Jerome Myers (1867-1940) and the "primitive" John Kane (1860-1934).

In sculpture, Gutzon Borglum (1871-1941) might be considered transitional to the styles of the present day, in his spirited and independent handling of all subjects from equestrians to the gigantic figures on Stone Mountain, near Atlanta, Ga., and in the Mount Rushmore Memorial in the Black Hills. Before him, however, the predominating character of the sculpture of this period was first definitely academic, the majority of our sculptors working at L'Ecole des Beaux Arts in Paris, and second, also French inspired, impressionistic. Of the first group the works of Augustus St. Gaudens (1848-1907) rank high for dignity and impressiveness, with delicacy and precision due to his early cameo cutting, and yet force and factuality that the French school was unable to obliterate. Daniel Chester French (1850-1931) was popular due to his sentimentality, picturesqueness and aspect of geniality, but he lacked the depth of expression in the works of St. Gaudens. Frederick William MacMonnies (1863-1937) expressed strenuous motion in his pieces, with a Carpeaux-like intensity, but lacking in monumentality. Herbert Adams (1858- ) displayed great charm in his early polychrome portrait busts, and still exhibits delightful works. A group of Indian sculptors were topped by Cyrus E. Dallin (1860- ) and Herman A. MacNeil (1866- ) and varied their efforts from highly dramatic to more contemplative interpretations. Paul W. Bartlett (1865-1925), the "American Fremiet", excelled in not only animal subjects but in romantic reverberations of Michelangelo. Other animal sculptors were Anna Vaughn Hyatt Huntington (1876- ), Edward Kemys (1843-1907), Edward C. Potter (1857-1923), A. P. Proctor (1862- ), Solon Borglum (1868-1922) and Paul Manship (1885- ) whose compositions, although perfect in craftsmanship, became more decoration than sculpture. James Earle Fraser (1876- ) popularly known for his sculptures for coins and medals, exhibits a monumental quiet in all of his sculptured pieces, large or small.

Two famous sculptors, among others, grew out of the Academy into the Impressionism of Rodin, namely, George Gray Barnard (1863-1938), the founder of the Cloisters, now a branch of the Metropolitan Museum of Art, and Lorado Taft (1860-1936). Barnard's powerful figures showed his early training as a jeweler and engraver, but displayed monumental simplicity and an emotional rather than an intellectual concept. Taft was not only a sculptor of sound figures, some of colossal scale, and of large numbers of figures so interwoven that the sculpturesque mass was not lost, but was also a beloved teacher and lecturer. Both men left the endowment of a genuinely awakened appreciation of sculpture to patrons and students alike. Many other names are worthy of mention, but regardless of merit and the fact that their efforts are far scattered in place, subject and style, they exhibit the fun-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

damentals of the plastic art as taught in Paris, Munich or in American schools whose teachers reflected the many academic and subsequent impressionist manifestations, especially those of Bourdelle and Maillol, who were transitional to more recent tendencies.

*1926 to date.* The works of present-day painters and sculptors are too comparatively recent for objective analysis or classification. Many of the names were well known before 1926. Among the sculptors who have been universally accepted are the following: Gaston Lachaise (1882-1935) following the symbols and semi-abstractions of French Post-Impressionism in an energetic full-bodied style; William Zorach, already mentioned as a painter, outstanding for his primitive simplicity and his directness of stone cutting. J. B. Flannagan (1898-1942), Alfeo Faggi (1885- ), Heinz Warneke (1895- ), Hugo Robus (1885- ), Jo Davidson (1883- ), Charles Rudy (1904- ), Richard Davis (1904- ), Mahonri Young (1877- ), Malvina Hoffman 1887- ), Hunt Diederich (1884- ), Robert Laurent (1890- ), José de Creeft (1884- ), Louis Slobodkin (1903), Gertrude V. Whitney ( -1942), Chaim Gross (1904- ), Henry Kreis (1899- ), Ahron Ben-Schmuel (1903- ), Concetta Scaravaglione (1900- ), Alexander Archipenko (1887- ), Carl Milles (1875- ), Merrill Gage (1892- ), Donal Hord (1902- ), and Alexander Calder (1870- ) are known for all aspects of modernism from the mobiles and stabiles of the latter, wherein varieties of expressions of the dynamic forces of nature appear in plastics and metals, to earthy factuality in social subjects, or the profoundly idealistic concepts of reality in the works of Gage. Carl Walters (1883- ) deserves special mention for continued excellence in glazed ceramic sculpture.

Present-day painters follow like manifestations in expressive forms ranging from cubist organizations to social subjects, the latter prevailing in more recent years, and representing all phases of the life of the American people from those stressing social propagandas in the works of William Gropper (1897- ), the Soyer Brothers, Nicolai Cikovsky (1894- ), and Benjamin Kopman (1887- ) to the intellectual literalism of Charles Sheeler and the objective panoramas of Paul Sample (1896- ). A typically American sense of fact, prevailing optomism, poise in the craft of painting, a strong sense of design, a sense of humor which is at times satirical, and confidence in the individual idiom appears variously and frequently unanimously in the works of the following men not already cited: Reginald Marsh (1898- ), Georgia O'Keefe (1887- ), John Steuart Curry (1897- ), Maurice Sterne (1877- ), Kenneth Hayes Miller (1876- ), Luigi Lucioni (1900- ), John Carroll (1892- ), George Biddle (1885- ), Charles Demuth (1883-1935), Jack Levine (1915- ), Alexander Brook (1898- ), Charles Burchfield (1893- ), Bernard Karfiol (1886- ), Aaron Bohrod (1907- ), Morris Kantor (1896- ), Bryson Burroughs (1869-1934), Glenn O. Coleman (1877-1934), Henry E. Mattson (1887- ), George Grosz (1893- ), Yasuo Kuniyoshi (1893- ), Jon Corbino (1905- ), Frederic Taubes (1900- ), Franklin C. Watkins (1894- ), Peter Blume (1906- ), Gladys R. Davis (1901- ), Vaughn Flannery (1898- ), Lauren Ford (1891- ), Katherine Schmidt (1898- ), Georgina Klitgaard (1893- ), Francis Chapin (1899- ), Doris Lee (1905- ), Rockwell Kent (1882- ), Waldo Pierce (1884- ), Henry Varnum Poor (1888- ), Fletcher Martin (1904- ), Ward Lockwood (1894- ), H. E. Schnakenberg (1892- ), Arnold Blanche (1896- ), Julian Levi (1874- ), Ernest Fiene (1894- ), Charles Hopkinson (1869- ), Lamar Dodd (1909- ), Grant Wood (1892-1942), Millard Sheets (1907- ), Peter Hurd (1904- ), Dan Lutz (1906- ), Philip Evergood (1901- ), Emil Ganso (1895-1941), Peppino Mangravite (1896- ), Walt Kuhn (1880- ), Max Weber (1881- ), Paul Cadmus (1904- ), Isabel Bishop (1902- ) and Ivan Le Lorraine Albright (1897- ), winner of the first medal for the best painting at the 1943 Victory Exhibition at the Metropolitan Museum of Art. Portrait painting other than that which has been done along with other subjects by the above mentioned men, remains in the hands of a score or so of Americans, among whom the names of Louis Betts (1873- ), Leopold Seyffert (1877- ), J. C. Johansen (1876- ), and Wayman Adams (1883- ), are outstanding.

Edward Bruce (1879- ) was selected to lead the government project in art in 1933, and a few years later Holger Cahill took over, the government commissions being chiefly mural projects. The earlier mural styles of Benton, Kroll, Poor, Barry Faulkner (1881- ), Eugene Savage (1883- ), Ezra

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Winter (1886- ), Hugo Ballin (1879- ), Conrad Buff (1886- ), and Jessie Arms Botke (1883- ) changed into what might be called a national style with Biddle, Sterne, Marsh, Curry and Boardman Robinson (1886- ), leading the pace. Many of the above named painters such as Marsh, Cadmus, Sloan, Benton, Marin, Kuniyoshi, Curry, Kent and F. W. Benson are also outstanding printmakers of today, and to this assemblage should be added the names of John Taylor Arms (1877- ), Thomas Handforth (1897- ), Howard Cook (1901- ), Robert Riggs (1896- ), Stow Wengenroth (1906- ), Adolph Dehm (1895- ), Harry Sternberg (1904- ), Wanda Gág (1893- ), Mabel Dwight (1876- ), Roi Partridge (1888- ), and Peggy Bacon (1895- ) among others who deserve mention. Among artists of animation, growing in number yearly, Walt Disney, who opened the Disney studio in 1923 ranks highest.

The National Academy today still stresses sound craftsmanship as its basis of selection by jury. Many who would not have been recognized formerly by the Academy are now members, such as Louis M. Eilsshemius (1864- ). In opposition are the moderns such as were selected by the staff of the Whitney Museum of American Art, the opposition not existing in the fundamentals of craftsmanship, but primarily in subject matter and interpretation. It is impossible to properly characterize present-day tendencies, since no two painters are alike, and since all the years since 1776 have been the battlegrounds of conservatism vs. liberalism subjective vs. objective and romantic vs. realistic, unless one may do so by indicating the comparative freedom from technical limitations, the catholicism of patronage, and the fusion of what might be called significant vision with significant form whether it be introspective, intuitional or representationally factual. **posy ring.** See JEWELRY.

**pot.** *Cer.* Container of clay, or production of clay articles. See CERAMICS I.

**pot furnace.** See GLASS AND GLASSMAKING.

**potential value.** A term coined to denote whatever latent values may be developed at any point by placing a visible accent there—as at the center of a circle. Its value lies in calling attention to the fact that aesthetic values are not always *created* from nothing by putting a spot in a certain place, but that a certain number of them are generated automatically by any line or spot that is set down on paper and are merely *developed* by the addition of other spots and lines. It is a concept that can be utilized in the solution of a variety of aesthetic problems. See Carl Thurston, *The Structure of Art.* —C.T.

**potne oeron.** See PRIMITIVE ART.

**pot-pourri.** A musical medley, a flimsy construction of a series of melodies.

**potter's wheel.** Wheel on which pottery is formed or thrown by hand. See CERAMICS I.

**pottery.** See CERAMICS II.

**pottery wheel method.** See terra cotta sculpture, direct method.

**pounce.** (1) The perforated design used in pouncing (q.v.). (2) The powder used in pouncing (q.v.).

**pouncing.** The technique of dusting powder through punched holes which define the outlines of a design.

**pozzolana.** A volcanic clay or cement has been given the name pozzolana, because of the presence of such material near Naples at Pozzuoli. It is found also in the Islands of the Greek Archipelago and along the Rhine. Such cements were probably used in the modelled figures and reliefs classified as stucco. They are made up of easily decomposable silicates formed by the action of volcanic fires. Mixed with lime, they provide a cement that is slow to harden and moderately strong. —G.L.S.

**pp.** See NOTATION.

**practical arts.** Generic term for the following fields of study: agriculture, domestic art (syn. *homemaking*), commercial art, and industrial art, all of which are characterized by "practical" activities used in everyday life.

**practical jokes.** See American folk forms, in literature.

**prägnanz, law of.** See PSYCHOLOGY OF DRAWING AND PAINTING.

**prāsāda.** See INDIAN ART.

**prayer modes.** See JEWISH MUSIC.

**prayer niche.** See mihrab.

**prayer rug.** Used by the followers of Mohammet. Design usually includes a representation of a mosque or place of public worship, showing the mihrab which is a niche in the wall of the mosque, so located that when the worshipper prostrates himself before it he will be prostrating himself toward Mecca. See ISLAMIC ART. —B.E.J.

**pre-classic dance forms.** *Pre-classic* is a contemporary term used to designate certain ancient dance forms. These dances were "pre-classic" in the sense that they antedated and influenced the growth of the classic ballet as a theatre art. They existed originally among the countless ancient dances of the common people of Europe and were performed in the villages, fields, and vineyards.

The pre-classic dances are distinguished from other folk-dance forms by the fact that they were adopted by European courts, refined and formalized until they constituted the court ball program. This new status led to their further function as basic material for the early ballet. As another result of the shift from village to palace, the music of these dances became the substance of the instrumental suite, first written for court ball accompaniment and eventually growing into the classic sonata and symphony. The dances usually included in the "pre-classic" group are *pavane, galliard, allemande, courante, sarabande, gigue, minuet, gavotte, bourrée, rigaudon, passepied, chaconne,* and *passacaglia.* —J.G.

**precision drawing.** See drawing.

**predella.** See altar; altarpiece.

**pregnance, law of.** See PSYCHOLOGY OF DRAWING AND PAINTING.

**PREHISTORIC ART.** In the earliest art, as in much of the art of the present, the student is frequently mystified by its significance. If in the latter, one feels that rich variations of the human mind are somehow revealed, in the former, one searches not so much for the dawn of aesthetic consciousness as for a record, and it is a brilliant one, of man's rise from savagery. Gordon Childe speaks of two great stages of development, that of a food-gathering and again of a food-producing economy. Naturally the arts reflect these activities. In a general way they correspond to the paleolithic and neolithic divisions of the anthropologist but since the rate of development as between the peoples of one part of the earth and those of another has been far from constant, varying in fact over thousands of years, a division by date is impossible.

Evidences of man's earliest activities are revealed by implements of flint which are widely distributed over the world. The beautiful leaf-shaped blades found in the rock-shelter of Solutré near Mâcon, France call for such exquisite refinement in the chipping that they might well be classified as works of art. Much earlier but cruder examples of flint chipping have been found at Chelles near Paris. This site has given the name **Chellean** to that period in the development of early man which some scholars believe extends back to 100,000 B.C. The flint industry extended into the age of metal as flint knives from Egypt and poinards from Scandinavia testify. Although there is considerable uniformity in the development of these implements, in America a peculiar type of flint-arrow was used quite unlike European or Asian examples. Those discovered at **Folsom** (q.v.), New Mexico are thought to date around 10,000 B.C.

The arts of representation seem to have had their origin with **Cro-Magnon** man probably some 25,000 years ago. Considerable credence may be given to the theory, held by Édouard Piette, that man's first attempts were made in fashioning a likeness from a free standing object. Later he turned to the more symbolic medium of drawing. Certainly the skill involved in the earliest sculptures surpasses that of the enigmatic signs painted on caves of equally early date. But the fact that from the very beginning there are various approaches to art forms gives rise to many problems. How complex are the motives which prompt man to visual expression? How dependent is any particular form of expression on qualities of race or outside influence? Is a work unskillful because it only approaches an ideal which has not yet been attained or because an indifference or decadence has set in Baldwin Brown who has made a penetrating study of the art of prehistoric times from the point of view of aesthetic theory concludes that always the initial movements in what are to become the arts are non-artistic. This element enters afterwards as a regulative agency. The various motives may spring from some instinct such as that of imitation, from pride, as in personal adornment, from some practical end to which magic and superstition have been brought or merely from the desire to convey information. As these forces each produce a result peculiar to itself and are present in the nature of man independent of each other it is futile to search for priority. In the acquisition of skill, however, and in the sharpening of the aesthetic instinct, there must be a continuity or evolution within each cultural unit.

The best work of Cro-Magnon man seems to have been largely prompted by the love of imitation but was soon modified by other forces. A female figure found at **Willendorf**, Austria, carved in the round form limestone and some three inches high, is representative of a large group in which the characteristics of sex are so exaggerated as to indicate a fertility cult. A similarly proportioned figure, but in relief and eighteen inches high, was found on the wall of a rock-shelter at Laussel in the Dordogne, France. Here she holds the horn of a bison which one is tempted to say suggests the crescent moon. Nearby was represented a male figure in profile treated with no fanciful or mystical suggestion. He wears a girdle.

But it was in the presentation of animals that this art reached full maturity. The best examples are concentrated in the Dordogne just north of the Pyrenees and also just south in Santander province at **Altamira** and Castillo in Spain. Osborn gives 16,000 B.C. as the approximate date for this art which is

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

distinguished from the earlier work just discussed by the term **Magdalenian** from the rock-shelter of La Madeleine along the Vézère River. This art is outstanding for its realism and some three hundred specimens of animals have been identified. The polychromy has been preserved by the deposits of lime which have seeped through the rock. The position of many in low dark recesses where they could be seen only with difficulty and the fact that the animals are often represented wounded by darts, suggests a superstitious origin connected with success in the hunt. The discovery of numerous incised drawings on stag horns, for which it is difficult to find a use, has led to the belief that these also were connected with some form of magic as sceptres for ritual occasions.

Further evidences of ritual and magic occur in representations of men dressed as animals as in a mimetic dance. A well known wall painting from Cogul near Lérida, Spain, represents clothed women surrounding, as in a dance, a small figure of a nude man. Here, however, there is manifested an entirely different aesthetic approach. This gives rise to baffling questions of relationships between sites classified by Obermaier as **Capsian**, from a place in Tunis, and the shelters mentioned above. Perhaps we have in these later Spanish examples evidence of a new migration from Africa and it would seem likely that the representation of the bow in Capsian art indicates a later date. North of the Pyrenees at Mas d'Azil there are indications of decadence. Imitation no longer seems important but now rather the emphasis seems to be on a symbolic expression for information. This is the approach which would lead to picture writing, hieroglyphics and a literature. Such an advance, however, would mark the more settled conditions of neolithic times.

Researches of recent years have greatly emphasized the importance of pre-historic Africa (see AFRICAN NEGRO ART). While Northern Europe was under a layer of ice and the Pyrenees were capped with glaciers, the Sahara enjoyed abundant rainfall. Rock engravings from Kef Messioner, Algeria and in Fezzan depict with the same extraordinary skill of Cro-Magnon drawings, numerous animals requiring woods and lush meadows for grazing. Closer parallels exist between examples of Capsian art in Spain and early Bushmen paintings from Rhodesia. It will be remembered that the Bushmen are the last survivals of the earliest peoples to have inhabited Africa. It is impossible to develop an accurate chronology between racial types, nor can we now believe that all art had its origin in a single source. Certainly large migrations followed climatic changes, some races have disappeared, others have fused into a stock which gradually evolved a new culture in accordance with the advances of civilization.

Nothing is more convincing of the penetration of eastern peoples into the west than the series of huge stones for burial and ceremonial purposes which extend from Asia Minor to the British Isles. There is also evidence that the custom spread eastwards to India. Of these monuments **Stonehenge** in England is the most famous. It consists of a great circle or cromlech about an altar stone arranged so as to tell the season of the year by a cast shadow; a principle similar to that of the sun dial. Astronomers have been able to date this monument around 1600 B.C.

The earlier development of time measurement in Egypt is emphasized when we recall that the calendar is thought to have been established there in 4236 B.C. The neolithic cultures of Egypt, especially the Gerzian of the upper Nile, are of considerable interest. Childe speaks of the Egyptians as the earliest farmers. Progress in spiritual life is indicated by the graves in which numerous amulets have been found. Examples of bulls' heads and falcons indicate the firm establishment of totemic clans. Of especial interest is a tomb at Hierakonpolis containing wall paintings. These are in the style of early decorated pots but announce the sepulchral frescos of later times (see EGYPTIAN ART).

Always there is the problem of foreign influences. Mesopotamian inspiration is evident in many of the late neolithic finds of Egypt and it is likely that the use of bronze came from that source (see MESOPOTAMIAN ART). Gold was the first metal to be used by man and beads of hammered copper have been found in Egypt which must date as early as 5000 B.C. but they were not fashioned by the aid of fire.

It is the pottery, however, which is of the most importance in determining early cultural centers and their connections. The study of these objects reveals certain parallel tendencies between Egypt, Sumer and the Indus region which argue for direct contacts between these important groups. It would be risky to assume definite dates for such relationships before the third millennium. What is important is that we have the roots of

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

three great civilizations, each with definite and individual characteristics, each a cultural unit derived from a mixed race in similar climatic conditions, and each making some contribution to the other.

From the material which has come to light up to the present time it would seem that a certain degree of priority might be given in the art of pottery, possibly even the invention of the potter's wheel, to a region in the upper reaches of the Tigris and Euphrates valleys extending westwards even to the coast of Northern Syria. Some of the finest pottery of antiquity comes from Tell Halaf. This is hand made, has thin walls fired to a considerable heat and is painted with conventional designs. One representation has been found of a man and a chariot. There also occur the winged solar disk so characteristic of Egypt and the double axe designs which are associated with Crete. There is, however, no evidence of the use of metal and the culture must belong to the fourth millennium or earlier.

The development of culture in Crete which is now thought to have been the center of early Mediterranean art extending even to the shores of Spain would certainly have been later. Sometime perhaps scholars will be able to decipher the tablets of baked clay which survive in Crete in great numbers. One found at Phaestos is unique in that each little picture of the pictographic inscription was pressed in by its own special seal.

But to return to the earlier centers in Mesopotamia we find that of the several sites in the highlands which have come to light within the last few years those of the al-'Ubaid peoples are especially significant. It is believed that these peoples migrated south as the rich delta lands became available and formed the stock from which the great Sumerian civilization sprang. Their pottery is allied to the finds at **Susa** belonging to the first of the two distinct neolithic periods which have been unearthed there. This ware exhibits considerable ceramic skill and may have been turned on a slow wheel.

The ware from **Susa** may be slightly earlier, 4000-3500 B.C. The designs are of the greatest interest being undoubtedly magical in content. They consist of circles, wave patterns, the maltese cross, conventionalized human figures and birds. The stylizations and shapes suggest an origin in basketry. Yet they are close to the abstractions which an accomplished culture always makes in order to better reflect the essential quality of the object as a symbol. We see in these painted pots the forerunners of the complicated symbols engraved upon seals of a later date and signs which eventually were converted into elements of writing.

If it has not been possible to distinguish precisely all the various stages which led up to the great civilizations of the Near East and the Indus Valley certainly the arts reflect definite contacts of one with the other. In the case of China and again in the Americas the problem is much more vague. Anthropologists have evidences of the existence of man in China from remote times but no art forms have been discovered prior to late neolithic times and these suggest the painted pottery of the Near East. Nevertheless the spiral and strange zigzag patterns have a distinctive quality of their own. Large quantities of such vessels have recently been unearthed in Kansu province. It is not a little bewildering to find just a hint of this ware in some of the pottery of the Americas. A small rain-god from the Pan Shan Find, Kansu province suggests the kacinas of the Hopi Indians; a burial jar from the **Diaguite culture** of Argentina has the same conventionalized finger ornament as a jar from the Ma Chang Find of the same province. But of these finds the unpainted tripod form alone announces the Chinese aesthetic ideal of the great Shang dynasty. The origin of the extraordinary accomplished and highly symbolic designs of this historic period, 1765-1123 B.C. are veiled in obscurity.

It is intriguing to follow some thin and disconnected parallels of these exquisite Shang motifs in the Americas but any attempt at definite conclusions as to prehistoric contacts around the Pacific area is impossible. There were probably many migrations into North America and thence down to the southern hemisphere. Unique in prehistoric sculpture are the stone seated figures found along a strip extending from Georgia to the Mississippi. They have round moon-like faces indicating a ceremonial image. There are many indications of Lunar worship among the American aborigines (see AMERICAN ABORIGINAL ART) some of the motives as the double axe (q.v.) suggest forms used elsewhere, others indicate a completely isolated evolution. It is strange that the potter's wheel so well known in China before the Shang dynasty was not used in the western hemisphere, yet bronze casting was well known among the Incas of Peru.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Whence came that art of bronze casting so magnificently developed by the Chinese? One must certainly take into consideration stylistic relationships between the bronzes of the Ordos region west of Peiping on the border of Mongolia and finds from Luristan in Western Persia or even closer connections with Scythian and earlier objects from South Russia. It can only be supposed that racial migrations carried the technique and an instinctive feeling for the designs across the steppes of Siberia into Mongolia. However, the migrations were not always to the east. We know that the Celts at one time inhabited the Black Sea region and in their turn carried this style westwards even to Ireland. Just what was added and what was lost in these migrations is impossible to say. The **Luristan** finds are not necessarily earlier than those from the Kuban in South Russia and yet it would seem likely that the art originated in Persia. In these objects we see how the old stone age interest in animals has given way to the geometric abstractions of the new stone age and then how it was rendered with all the aesthetic force of the discovery of a new medium superbly adapted to the expression of the symbolic ideas. Human headed monsters and grotesque combinations of parts of different animals are molded into masterpieces of pierced design. The further away from Persia the objects are the more intricate become the patterns.

In Europe there are two important centers connected with the progress of this animal style westwards. They are **Hallstatt** in Austria and **La Tène** in Switzerland. There are evidences that the Dorians who invaded Greece from the North before 1000 B.C. had been in contact with this culture and, of course, in historic times Greece was constantly aware of the peoples of the Danube and Black Sea region. Thus we see how complicated and uncertain becomes the problem of tracing stylistic connections.

The **Viking style** (q.v.) in Scandinavia together with the zoomorphic ornament of the Celts certainly received the basis for its peculiar forms as the result of racial migrations. Although south Russia served as a center of dissemination it is impossible to trace precisely the extent of the creative accomplishment there.

Perhaps the most remarkable pre-historic bronzes are the **Luhrs** or trumpets from Denmark. These are occasionally eight feet in length but are riveted together, precision being obtained by hammering. It is likely that they date from the iron age. Mention should be made of two gold horns discovered in Denmark but no longer extant. These were incised with designs which have been variously connected with the East. One, however, had a runic (q.v.) inscription which indicates a date of about the 5th cent.

From the above it will be seen that the student of prehistoric art is confronted with problems beyond his grasp. However, were it not for that quality, unique in man, of expressing his ideas visually, our knowledge of the rise of civilization would be more limited than it is. Every year produces some new evidence bearing on the process. When we recall that the entire subject does not antedate the 19th cent. and, one might almost say 1862 when M'sieur Lartet began his excavations in Southern France, one is impressed with the strides that have been made. Especially important have been the discoveries in the Near East and the Indus Valley since 1920. Of the enigmatic sculptures of Easter Island and other problems too numerous to mention, one may only hope that the clues may be forthcoming. But this much the arts of prehistoric times reveal; man has roamed over the surface of the earth for thousands upon thousands of years and in his evolution from a lower form of life to a civilized human being the need for art has ennobled and quickened the change. **pre-Khmer art.** See INDIAN ART.

**preliminary matter.** *Book.* The pages of a book or the matter on them preceding the body of the work. Usually numbered in Roman numerals. —H.E.S.

**prelude.** *Mus.* An overture or introduction to a musical drama; an instrumental composition such as a fugue, suite, or partita.

**preparation.** See PSYCHOLOGY OF ART.

**Pre-Raphaelitism.** A movement in late 19th cent. English art and literature, referring especially to painting. From the point of view of form, pre-Raphaelite painting was based on mutually conflicting doctrines, of which one or the other alternately prevailed. Often the artists imitated Florentine *quattrocento* (q.v.) painting, and especially such predecessors of Raphael as Gozzoli and Botticelli, and from this they derive their name. They considered art before Raphael more sincere and genuine, less artificial, mannered, and formalized than it was thereafter. More frequently, however, they merely emulated the spirit of the *quattrocento*, conceiving their forms with a naturalistic and almost photographic vision. In either case, they opposed all academic rules and conventions of drawing, composition, and color, which in England were then based upon Raphael, Reynolds, the Carracci, and antique sculpture.

From the point of view of content, the pre-Raphaelites were sentimentalists and popular-romanticists who preferred to depict moral, religious, historical, or anecdotal subjects, or literary illustrations,—especially of Shakespeare and Dante. Holman Hunt's *Light of the World* is a good example, wherein naturalistic form is employed in the service of a sentimental and popularized idealism. Hunt's *Hireling Shepherd* and *Scapegoat* and his scenes from Shakespeare are also typical. His *Finding of Christ in the Temple* and *Christ Among the Doctors* illustrate the pre-Raphaelite belief that in depicting a historical scene the artist must be true to all details of our scientific knowledge concerning the event. He went to Palestine to discover needed facts of costume and setting for such pictures.

A distinction is made between the pre-Raphaelite movement and the **Pre-Raphaelite Brotherhood** (P. R. B.). The Brotherhood was founded in 1848 by Holman Hunt, Sir John E. Millais, and Dante Gabriel Rossetti under the stimulus and inspiration of Ford Madox Brown, who was never himself a member of the Brotherhood. The founders were soon joined by two other minor painters, a sculptor of no great success, and a writer, William Michael Rossetti, brother of the more illustrious, painter-poet Dante Gabriel Rossetti. The members of the Brotherhood defined the aims of pre-Raphaelitism, held several exhibitions, were vigorously defended by Ruskin, and gradually drifted apart in the late 1850's. Individually Hunt and Brown continued the original aims of the Brotherhood throughout their lives; Millais went over to the academy, Rossetti gradually developed a very personal idealism, a little less photographic than the others and more similar to Botticelli. New followers soon began to imitate one or another of the original Brotherhood and, as representatives of the movement, continued pre-Raphaelitism to the end of the century. The most notable is Rossetti's pupil Sir Edward Burne-Jones. Others include Frederick Sandys, J. M. Strudwick, Spencer Stanhope, Evelyn de Morgan, Arthur Hughes, Bryam Shaw, Wiliiam Windus, Matthew Lawless, Charles Collins, and W. S. Burton. See ENGLISH ART. —L.D.L.

**pre-Romanesque art.** See Ottonian art; GERMAN ART.

**presbyacousis.** The progressive loss of hearing in the upper register due to age. From early childhood up to about middle age a normal individual under favorable circumstances may hear tones as high as 20,000 vibrations per second. From middle age this upper limit of hearing falls progressively so that at the age of 70 under equally favorable circumstances he can not hear tones above 4,000; that is, there has been a gradual change in his hearing of tone quality by the progressive loss of four-fifths of the overtone register which he could hear in the prime of life.

"This finding is of almost unbelievable significance for the hearing of music, as it is also to some extent for speech. In this loss of capacity for discrimination of tone quality, age has no respect for professional standing, training, or knowledge. It is a physical law in that the hearing curve represents the degeneration in the harp structure of the ear. This specific law is in accordance with the general biological law of degeneration; namely, that degeneration of function begins with the latest acquired and most delicate structures.

"It is comforting to know that the register which remains practically normal is the region in which the fundamental of most of our musical tones occur and within which speech sounds are most significantly differentiated. The loss comes upon us so gradually that we make corresponding adaptations in hearing and would perhaps not be aware of it in ordinary experience, radical as it is.

"I confess to feeling a little like a bull in a china shop in bringing this law to the attention of artists who are enjoying the rich musical life in old age. The greatest comfort lies in the realization that our subjective hearing, as in the case of deaf musicians, still plays a very important role." (From *Music Educators Journal*, May, 1938.) See C. C. Bunch, "Age Variations in Auditory Acuity" *Archives of Otolaryngology*, vol. 9, 1929, pp. 625-636; N. H. Kelley, "Study in Presbycousis; Auditory Loss with Increasing Age and Its Effect on Perception of Music and Speech," *Archives of Otolaryngology*, vol. 29, March, 1939, pp. 506-513; National Health Survey 1935-36, Hearing Study Series Bulletin 6, "Sex Differences and Age Variations in Hearing Loss in Relation to Stage of Deafness"; Division of Public Health Methods, National Institute of Health, U. S. Public Health Service, Washington, D. C., 1938. —C.E.S.

**presentation** (L. *praesens*, that is before one, in sight or at hand). Sensory appearance; exhibiting or being exhibited to sense-perception; serving or ability to serve as a stimulus to sensory experience. One of the two modes by which works of art are transmitted to the mind of the observer or appreciator; the other being *suggestion* (q.v.). In a painting, lines, light and dark areas, and colors are *presented* or *presentative*, while associated meanings, things represented, etc., are suggested. Thus a work of art may contain both presented and suggested factors. —T.M.

**primary colors.** See COLOR.

**prime interval.** See interval.

**Prime Minister.** See ORIENTAL MUSIC.

**priming.** See ground (1).

**"primitive", American.** See EARLY AMERICAN ART.

**PRIMITIVE ART.** It is unfortunate that the term primitive has been vulgarized into one of the vagaries of expression with which the vocabulary of art is filled. One speaks of "the primitives" to indicate a school in painting which developed just prior to the renaissance interest in space. Or again it is customary to refer to various phases of the work of the folk artist as primitive. Formerly it usually carried some note of condemnation but more recently the expression has come to convey an element of emotional sincerity. This indicates a keener understanding of the nature of art and leads to the more precise use of the term followed here. Primitive society is one in which the conventions, and individual acts dependent upon them, are based not on purely physical phenomena but rather upon superstition. This results at times in a passionate appeal to a protective spirit. Primitive art as a reflection of this society disregards physical accuracy and, although following established traditions, has an intuitive, elementary and mystical existence. As primitive man participates more

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

than civilized man in natural phenomena so his art is instinctive rather than intellectual.

The appreciation of this quality is of recent development. Of course in the 18th cent., Europe was intrigued by the idea of the noble savage and again in the nineteenth century, the desire to escape from the artificialities of civilization made the South Sea Islands idyllic retreats of romance, but only with the 20th cent. did the mind of primitive man, and hence his art, come to have a real significance. This interest was largely aroused as a result of Bergson's philosophical writings in which he placed emphasis on instinctive reactions rather than upon factual knowledge. Again the increasing interest in psychology has produced attempts to discover parallels in the development of the child and the development of the race, which has caused primitive man to come under closer observation. As in the study of pre-historic man, whom primitive man only vaguely resembles, great progress in understanding has been made in recent years. Whether an interest in these related things has developed a taste for the art, or a realization of the art has caused these interests, is a futile question. Each is a part of the other.

But are the factors which lay at the source of primitive art still active in the mind of civilized man? Here we have a divergence of opinion among ethnologists. Lévy-Bruhl, a foremost exponent of the French school, sums up the situation. He says, "Do the collective representations of the communities in question arise out of higher mental functions identical with our own, or must they be referred to a mentality which differs from ours to an extent yet to be determined?" It is this latter supposition that he has tried to analyze, while the English scholars under the influence of Taylor, whose great work *Primitive Culture* appeared in 1871, have pursued the former. Lévy-Bruhl feels that the English school of anthropology in trying to show the relation between "savage" and "civilized" mentality, and to *explain* it, has been greatly hindered. Franz Boas, so prominent among American scholars, suffers the same criticism. Perhaps our reactions to primitive art could furnish an important clue to this question. The difficulty here lies in a lack of free spontaneous emotion which is especially characteristic of civilized peoples. But is it not significant that the modern artist has found in recent years, magnificent inspiration in the art of the savage?

Yet however varied may be the fundamental traits of the mind it must be obvious to all that different peoples react very differently to the same phenomena. The individual is certainly conditioned by the society to which he belongs and we can understand the art of any society better if we can follow its historical evolution. But this is never completely available. Obviously there are other conditions which must be taken into consideration. Environment, physiological, psychological and social factors all have an important bearing on ideas and in these there is great variation. Yet notwithstanding this, it is the general similarities in widely scattered areas and peoples which is astounding. This gives rise to the feeling of a unity in the human race but also raises the difficult question, when similar forms exist, of parallel developments or contacts through migration. Evolution of art forms has by no means followed a single formula. The study of peoples and even civilizations emphatically reveals many survivals, that is, ideas which were once of use and persist long after they have lost their usefulness, many mixtures of both retarded and advanced ideas, and many concepts which can only lead those who follow them into a blind valley. Perhaps this latter is true of primitive peoples, yet all societies seem to have passed through that stage and the solution has not yet been found.

In any event it is obvious that the aesthetic reactions of primitive man are limited by the knowledge at his disposal, and primitive man everywhere has not learned to view physical data objectively. He does not think logically, though he may have a complicated process of reasoning. His mind is made up of logical and prelogical elements which are subject to what Lévy-Bruhl has called the "law of participation". To the primitive there is a mystical element in every existing object and he, himself, is but a helpless part of a great spiritual entity. This concept suggests the much used term **animism.** Although the precise meaning of this word is subject to controversy it is at any rate the key to primitive art. Frazer's magnificent work the *Golden Bough* is filled with examples which illustrate this characteristic. It is perhaps inaccurate to assert that the primitive imagines in all forms of natural phenomena exactly the same elements, "souls", "spirits", "intentions", which they themselves have experienced, but there is no denying his certainty of a pervasive spirit. Many peoples believe in a multiplicity of souls and

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Lévy-Bruhl feels that the concept of the "soul" appears only in peoples of a relatively advanced type. Earlier, in accordance with the principle of participation elaborated by Lévy-Bruhl, an individual felt himself mystically united with the animal or vegetable species which became his **totem.** He may have felt this kinship in many instances as a "dream-soul", a "forest-soul" and so on. This authority objects to the concept that, "One and the same soul" manifests itself as "life on the one side and phantom on the other". That, to him, is too simple an explanation and does not take into account his theory of prelogical mentality. According to his general law of participation, the primitive has no objection to contradiction, i.e., a person may be two things at once. Hence, to quote Lévy-Bruhl again, "The individual, while living participates in the *kra* that inhabits him, that is, he to a certain extent is this *kra,* and at the same time he is not . . . At the moment of death, this participation comes to an end."

To the primitive there is no insuperable barrier separating the dead from the living. Everyone is aware of the great amount of attention paid to the dead by all peoples, particularly in the great ancient civilizations of Egypt and China. The persistence of basic ideas and practices in China makes a study of Chinese civilization especially illuminating. J J. M. de Groot's *The Religious System of China* is a valuable document for the study of the primitive mind, yet China is recognized as producing one of the most cultured of civilizations. The belief of the mingling of the dead with the living is part of the general concept of the spirit world which must be grasped as a preliminary towards understanding the art.

This is because of the tangible quality of art in which there may at the same time exist a symbol of an intangible element, or, even more positive than that, in which the spirit may actually be embodied. To treat in detail the variations which result from the general attitude described above is beyond the scope of the present study. When, however, it is understood that the spirit of the dead may reside in a tree, in an altar, or in a statue, one begins to grasp the significance given to these things. Again when it be understood that a representation actually had the vital quality of the thing it represented, it takes on a new meaning. The chief motive in the creation of art forms was to appease the spirits, either those of the phenomena of nature or those of one's ancestors, for man is in need of their favors. He does this by giving to each spirit a material object where it may reside, and thus, in venerating the object, he is in reality placating the spirit. This object is called a **fetish.**

The ability to partake in mystic fashion of the essence of the animal or vegetable species whose name he bears is the basis of the concept of the **totem.** Each totem is mystically bound to a strictly defined locality and becomes a powerful social force for it holds a group together. One must not believe that the ancestor of the totemic group was exactly like the appearance of the animal by the same name. They may have been mythical animals which had a mystic share of both the animal and the human nature. The feeling of unity within the social group was very strong, and this is important in so far as it did not allow the individual freedom to create an art form as a personal variation of the symbol. An awareness of the sacredness of the group, of the established ritual and symbolism of the art forms was often learned by long and arduous discipline to which each member of the tribe must be subjected.

**Fertility cults,** both of nature and human, are of universal importance and are connected with solar and lunar worship. All peoples have felt a kinship between man and nature which has resulted in an anthropomorphic attitude towards nature. That is, the thought arises that various spirits are the off-spring of more important deities and usually the first great union was that of Heaven and Earth. In concepts such as this involving a narrative theme folklore is peculiarly rich. The visual representation was more impressive as a specific symbol although narrative incidents of great complexity were often developed. These are sometimes so stylized that interpretation is possible only to those familiar with the theme. In any case a precise significance for any art form is an extremely risky supposition.

The oldest symbols, no doubt, represented the great forces of nature: the solar disk, the alternating light and dark cycles of the moon, the elements of air and water depicted by birds and fishes or wavy lines. Eventually came the idea of space and direction as indicated by the equal armed cross. Symbols of life, generation, and divinity were woven into textiles and baskets and painted on pottery. No doubt a feeling for greater vitality, a dynamic forcefulness, resulted in the forms of the spiral, the swastika and the so-called

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Greek fret. The **swastika** has been spoken of as the symbol of the sun's movements. It is probably indicative of a combination of ideas, such as the cross of direction and the rays of the sun. Certainly it is one of the most universally used and enduring of symbols. There is a kinship between it and the whorl although this latter symbol was frequently shaded in alternate light and dark, suggesting the phases of the moon or, as in China and Japan, divided into one dark and one light section indicative of the ***Yin*** and ***Yang***, or male and female principle.

The evolution and interpretation of the two basic Chinese motifs, the ***lei wen*** and ***t'ao t'ieh*** are extremely important for they represent the furthest development of two generalized primitive concepts, the one having primarily to do with the forces of nature, the other with the forces of life. They both became highly abstract cosmological symbols and perhaps furnish the basis for an understanding of the devious and mystical symbols connected with the moon. (See Hentze, Carl, *Mythes et symboles lunaires* [Chine, ancienne, civilisations anciennes de l'Asie]; also Hentze, Carl, *Objets rituels, croyances et dieux de la Chine antique de l'Amérique*). Hentze has brilliantly displayed how the well known **glutton motif** reveals the lunar cycles. In swallowing a figure it stands for night and obscurity and in ejecting it forth it stands for birth and regeneration. This motif is popular not only in the bronzes of ancient China, and in the art of pre-Columbian America but survives with perhaps a different meaning in the sculpture of the Middle Ages in Europe. Again the urge to represent disconnected parts of animals as though they had been bitten off would seem a part of this same concept. This also occurs in the motives of medieval art, a survival, no doubt, from the barbaric style of Northern Europe into which many aesthetic forms penetrated from the Near East.

It has been said that Egypt invented plant design and Mesopotamia subjected the animal kingdom to art. We have now learned that any priority of this sort is relatively unimportant since the real source is an instinctive feeling within mankind. Goodyear has brought out some surprising relationships as regards Egypt in his *Grammar of the Lotus* and Frankfort's recent work *Cylinder Seals* is revealing as to the richness of animal symbolism in Mesopotamia. Yet the source of cosmological symbols remains a mystery. Specific animals are related to certain forces, but in this there is naturally great variation probably depending for the most part on the predominance of certain animals in certain regions. One thinks of the Chinese symbols of the tortoise, red bird, dragon and tiger for the four points of the compass, the four seasons, the four elements and even four organs of the body (See SYMBOLISM IN FAR EASTERN ART). Again, one recalls the lion of Babylon or the eagle of Egypt as solar symbols, the bull in Crete as the lunar sign, though in Egypt he at times represents the sun, and the complicated symbolism of the serpent. Never in primitive thought is this considered evil. The rabbit, the bear, and the tiger have all been thought of as lunar animals. It was relationship such as these which developed the signs of the Zodiac. The imagination, no doubt, evolved fantastic creatures, chimeras, sphinxes, garudas and others, in order to combine several ideas in one symbol. The Persian esp. favored such combinations. The **hippolectryon**, a combination of cock and horse, must have been a solar sign. The **bird and serpent** is another important combination very generally used. It is esp. featured in the plumed serpent of the Mayans and is related, of course, to the Chinese dragon and the medieval basilisk. Finally, there is the symbol of the tree with its many implications.

When the superiority of man and the nobility of his form becomes recognized, primitive art is at an end, yet this has not been a gradual evolution. One of the fine examples of the human form in sculpture is the pre-historic engraving of a man from the rock-shelter of Laussel in France, and who is not aware today of the animal symbols for the evangelist! It is commonly said that the greatness of Greek civilization depends upon its relative freedom from the mystical forces of nature. This anthropomorphism was to be a great heritage for civilization, but the change from primitivism to the theosophical tendencies of the East was likewise a process of civilization and a heritage perhaps equally great.

A study of primitive Greek art is esp. fascinating in that it announces this final achievement. The exhaustive researches of Cook in his work *Zeus* reveal again and again how primitive concepts gradually fade into myth and fancy. The legend of Zeus and Europa, a survival of the early belief in the marriage of the Sun and Moon, is but one of many examples. The relationship between man and nature was often represented by a

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

human figure between two animals. To this symbol the Greeks gave the name *Potne Oeron*. Collum, in a study of a megalithic monument of the Iron Age at Tressé, suggests that the thought of this symbol is similar to the snake-hood over the seated Buddha. But as a true primitive sign it probably had to do with a lunar cult.

The study of the gradual emergence of the primitive mind into other attitudes belongs to the study of each individual civilization. It will be of interest, however, to look briefly at the art of some of the peoples who even today have not passed beyond this stage. For the most part the vitality of their beliefs has been lost, however, and the true primitive concept is a rapidly disappearing phenomenon.

The Bushmen of South Africa are probably a unique survival of a pre-historic race. Their drawings suggest the Capsian art of Spain but its significance has been lost among the present survivors. They were driven at an early date from Northern Africa to the South by the negro. The finest art of the African negro was produced by the great empires of Yoruba, Dahomey, Ashanti and Benin. This region of Western Africa is agricultural and consists of a charming landscape not overwhelmed by forest. Here the great art of bronze casting was developed as early as the 15th cent. Some early examples are portrait heads showing tattooing and fine characterizations from Ifé, Nigeria. Heads of a similar type exist in terra-cotta. The Yoruba peoples had an unusually rich mythology said to contain some 600 gods and a supreme being but their art passed beyond purely religious expression and contains secular subjects. The Benin bronzes are later and not infrequently represent the Portuguese from whom they may have learned some technical improvements in their method of bronze casting. The 18th cent. marks a definite decline among these peoples even to extreme fanaticism and human sacrifice. It is noteworthy that sun and fire worship so common among primitive peoples had here completely disappeared. The gold dust weights of the Ashantis are often amusing bits of genre, but even more animated are the wood carvings from the Congo. The Batshisks are famous for their carved wooden chairs. Wooden masks for ceremonial use are common among most tribes but the Ashantis seem not to have used them. The very beautiful ones of the M'Pongine even suggest the exquisite examples of Japan. Often the figure sculpture was not for use in a cult but rather as charms to keep away evil (see AFRICAN NEGRO ART).

The Aborigines of Australia, as a hunting people, have not a highly developed art, although their social organization is complex. Oceania (q.v.), however, offers many distinctive characteristics which differentiate the Melanesians, Micronesians and Polynesians. All possess a great love for surface ornament and utensils are richly decorated. The Maori especially exhibit great skill in carving and a delight in facial tattooing (see Maori carving). In the Marquesas Islands some of the men are completely tattooed even to lips and eyelids.

In the Americas the Indians of the northwest coast, especially the Kwakiutl (q.v.), Haida and Tlingit (q.v.) tribes developed a rich art. Totem poles are the outstanding feature and served as a sort of family crest. Sometimes a mythological story was intended by the carvings but always the ancestral animals served as a basis. The peoples of the southwest developed a distinctive culture with perhaps decorated pottery as its finest manifestation. Pottery is also distinctive of the various cultures which extended even to the tip of South America. The great civilizations of the Inca and Maya (qq.v.) deserve special treatment but they are merely outstanding among the many cultures of the Americas before the coming of the white man.

All primitive art is marked by a singular indifference to realism. Pleasure in imitation is doubtless present but soon becomes overshadowed by other qualities. An abstraction based on essential characteristics is found more forceful and appeals to the final controlling influence of pattern. The desire for symbolic expression and for decoration are the dominant characteristics. Sometimes each is quite independent of the other, sometimes the one becomes merged with the other. A pleasure in craftsmanship must have been at times the sole motivating force. There is an intuitive quality in man which delights in rhythmic relationships while at the same time he enjoys adapting those combinations of symmetry—double, inverted, or otherwise—to the exigencies of different materials. Much has been made by recent writers of the idea that art originates as a kind of by-product of some utilitarian occupation. Man needs a basket and takes pleasure in making it beautiful. He must have a dwelling place for a spirit and he creates a form possessed

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

with beauty. He wishes to convey a message and finds it more effective when it appeals to the aesthetic sense. He finds that by creating beauty he pleases and that, too, may have a practical end. If his peculiar aesthetic reaction is lost to the "civilized" individual it may be because the latter is too superficial to grasp it or his mind too warped by prejudice. For primitive man is still man. And though we may find the workings of his mind quite different from our own—so different that an interpretation of his art is extremely dangerous—and though his artistic expression may at times seem to have become strangely perverted as in the "disfigurement" of the body, still the quest for beauty must remain a fundamental instinct of the human race. See Adama Van Scheltema, F., *Die Altnordische Kunst,* 1923; Boas, Franz, *The Mind of Primitive Man,* 1916; Boas, F., *Primitive Art,* 1927; Catlin, George, *North American Indians,* 1903; Clawson, Hamilton P., *By Their Works,* 1941; Collum, V. **primitive loom.** In the Swiss Lakes we find warp weights judged to be perhaps 10,000 years old. The Swiss Lakes looms must have been similar to the loom pictured on the famous Grecian vase illustrating Penelope weaving the Tapestry she unravelled each night. In Scandinavia skulls are used as weights. In Iceland the same primitive loom is used today.

The primitive loom covers a span of 10,000 years. We find this same loom used by the Haida tribes of Coastal Alaska. It doubtless came into Alaska from Siberia.

The primitive loom was used by the Aztecs in Mexico probably before the birth of Christ. We have few fabric relics of the Aztec art which date before the Spanish invasion but we have evidences in their codices that weaving of cotton was of ancient date. —G.W.R.

**primitive music.** The term *primitive* is used in describing the music of societies which have attained only a comparatively low cultural level, whether those societies be prehistoric, historic, or contemporary. Studies of primitive music make use of the methods of comparative musicology. The findings of such studies have value not only in the light they may shed on the music of higher cultures but in the contributions they make to such other sciences as ethnology and anthropology.

Primitive music must be studied, in the cases of prehistoric and historic cultures, from artifacts, archeological remains, occasional pictures, and verbal descriptions of musical instruments, systems, and usages. Very little actual music, either as a tradition or in notation, is available. The music of the ancient Mediterranean civilizations — Ur, Chaldea, Babylon, Egypt, the peoples of the Old Testament — have been studied in this manner.

In the case of contemporary primitive societies, the music of the African Negro and the American Indian furnish the best known and most studied examples of primitive music. Here again, the music does not exist in notation, but must be phonographically

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

recorded for study, analysis, and transcription. Difficulties of transcription grow out of the fact that primitive scales and rhythms often fall into patterns which defy western notation, and such music cannot be reproduced on western musical instruments. —T.M.F.

**principles of design.** See design.

**principal vanishing point.** See PERSPECTIVE.

**principal visual ray.** See PERSPECTIVE.

**print, in.** *Book.* A book that can be obtained from the publisher. A book is out of print when no copies can be so obtained.

**printed notation.** See NOTATION.

**printers' mark.** *Book.* The trademark or device of the printer, sometimes on the title page, sometimes on the last page.

**printing, intaglio.** Printing in which the design is formed by ink rubbed into incised lines and areas below the surface of the plate. This is the opposite of relief printing. —K.K.

**printing, planographic.** Printing from a plane surface, the design being formed by areas which have an affinity for the greasy ink on the roller.

**printing, relief (or cameo).** Printing from ink rolled onto a raised surface, such as type, woodblocks, etc.

**PRINTS AND PRINT PROCESSES.** Prints are the product of processes that permit multiple examples of a design. For all types an inked design on a plate or block is imprinted on paper, usually by means of a press, in a manner closely approximating the printing of a book page. Since the earliest time prints have been associated with book printing. Probably the first woodcuts were an effort in the early printed books, to provide by a cheap method that could be combined with type, a substitute for the miniatures which had adorned manuscripts. Later, prints were a means of reproducing drawings. Today they exist in their own right as an art form. Many of their technical charactersitics have been adapted to commercial printing processes.

In no other art expression is an understanding of processes and the peculiar opportunities and limitations of the mediums so essential to judging the final product. So true is this that print collectors and connoisseurs are sometimes inclined to judge a print more on its excellence of technique than on its purely aesthetic expression. From the art point of view, both must be taken into consideration: a fine design in a print, aesthetically speaking, would be lost if not expressed with all the richness and possibilities of its medium, and inferior, if the printing process were not well performed also. A print is, accordingly, a harmonious blend of highly exacting requirements in artistic conception and execution, and in mechanical skills and manipulations. The work of creative art is the finished print, product of all the intermediate processes, creative and mechanical, which go into turning out the finished print on paper. In that final form it must be judged as an original work of art.

Print processes are many. Those depending on pressure for the impression fall into three general classifications according to process: (1) **relief process**, in which the impression is made by a line or area that stands out from the background of the block, carries the ink and under pressure of press or rubbing transfers it to the paper (includes woodcuts, wood engraving, chiaroscuro prints, linoleum cuts, Japanese prints, and the commercial zinc cut, as examples); (2) **intaglio process**, in which the line or area that makes the impression, cut into and lower than the general surface of the metal plate, holds the ink which is drawn out on the paper in printing by the great pressure of the press (includes engraving on metal, mezzotint, etching, aquatint, drypoint, etc.); (3) **planographic process** in which there is no appreciable difference in level between the printing area and the general surface, but in which the area designed to print has been chemically treated so that it retains ink which transfers to paper under pressure (includes lithography on stone, most used in fine art prints, and on the plates of metal and other material which have wide commercial adaptation). Not dependent on pressure, but classed also as prints because producing multiple examples by a related process are silk screen prints (serigraphs) and other stencil print variants, used commercially and in applied arts, and adapted also to creative art expression in wide variety.

Chronologically, print processes have been developed and had vogue according to contemporary artistic needs and tastes approximately in the order given below. Certain types have enjoyed popularity for a time and then have fallen out of fashion. Today a

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

variety of print processes are appreciated and employed by artists, and all methods used in the past are understood and could be used today. Preferred are lithography, block printing with wood or linoleum, etching and aquatint, engraving, probably in that order. Serigraphs have been gaining popularity among artists in the U. S. since ca. 1938 as a creative art medium.

**Wodcuts, block prints.** This medium, much used by early printers as book illustration, either left in black and white or colored by hand, consists in cutting away the wood (commonly cherry, pear, beech, apple or sycamore) of a block cut along the grain, leaving in relief the lines and areas which, when inked, will leave their impression on the paper. It is probably the oldest print process and dates from the 14th cent. The reverse may be done, incising the lines of the design, which remain as white outlines or areas in the printed surface. Usually a press is used, but pressure of any method, as rubbing, will suffice. Early woodcuts were predominantly outline designs. Modern woodcuts are usually arrangements of light and dark areas with great possibilities of decorative effect. The quality of the woodcut lies in the crisp contrast of dark printing on white paper.

The **linoleum cut**, printed from a wood block on which fine quality linoleum has been mounted and its surface cut exactly as in a woodcut, is a 20th cent. development and is easily worked. For fine work it is less satisfactory than a wood block.

Albrecht Dürer excelled among early artist-designers of woodcuts. Not a favorite medium in its simple form after the 16th cent., the woodcut was revived most effectively for its decorative possibilities by Paul Gaughin in the late 19th cent., and for the same reason has been generally popular among contemporary artists. Sharing popularity with lithography and etching in countries of Europe and in the U. S., the woodcut has been the principal print medium in contemporary Peru and Ecuador, and an important print process in Mexico.

The woodcut can be used with several blocks, keyed to print exactly in register, and each one inked with a separate color, to produce color prints. In the past, two important variations depended on several blocks used in printing:

**Chiaroscuro.** As the woodcut had been first used as an inexpensive substitute for the miniaturist's illustration, when printed books replaced manuscripts, the chiaroscuro prints, relying on tonal effects to depict form by values as the name implies (light-dark), appears also to have been a less costly substitute for the wash drawings in line and tone which the masters of the Renaissance produced and which were greatly appreciated by connoisseurs.

By multiple examples, chiaroscuros helped to satisfy the taste for drawings which there were not enough fine originals to meet, as well as allowing their enjoyment to a wider public. In some cases the chiaroscuro prints appear to have been done after celebrated drawings; in others they were apparently produced as art works in their own right. Essentially they are wood cuts, in which early examples are in line, touched up by hand after printing with white and a tone, closely approximating the drawings they resembled. Soon, however, several blocks, keyed so they would print exactly one over another, were used to print one or more tones, usually sepia, browns, greys or greens, to produce the effect of multiple values of a wash drawing. Chiaroscuros were especially popular in the 17th and 18th cents. in Italy, and were produced also in northern Europe, usually with the addition of outlines, sometimes from etched or engraved metal plates, to complete the compositions.

**Japanese prints.** These prints from woodcuts, which at first were limited in number of colors, developed by the height of their vogue a great range of colors, each one applied by a separate carefully keyed block printed by rubbing. They were a popular art form of the late 18th and 19th cents. in Japan, devoted principally to actors' portraits in famous roles, and a little later to scenery. Woodcuts, with multiple blocks for color, were also produced in China, probably from a very early period. Less is known about Chinese prints than about the Japanese, however. They continue to be produced in Japan. The subject matter has become more varied, the technique more adroit; but generally speaking, the art quality has deteriorated as they tend to fall into literal illustration. The elaboration of their multiple printing has seldom been rivaled in the western world, though essentially any color print produced from woodcuts is identical in process. Their design and decorative qualities have had notable influence on Western art through such painters as Van Gogh, Gauguin and Whistler.

**Wood engraving.** Known early, but first adapted brilliantly to delicately representing

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

tonal effects by Thomas Bewick in the 18th cent., and by Timothy Cole in the late 19th and early 20th cent., wood engraving permits most subtle and varied effects. Essentially the process is the same as that of the woodcut in that it is a relief process. The work is done on the end of a finely grained hard wood block cut across the grain, usually of box wood, with delicate engraving tools and fine lines which give the greatest delicacy with an infinite range of tone as well as lines and solid areas. It has subtlety and delicacy where the woodcut has decorative boldness. It enjoys considerable popularity among contemporary artists.

**Engraving.** This method of printing from metal, incised directly with a sharp tool, used by early Italian and German print makers, probably was discovered in the shops of gold and silversmiths or armorers as a means of recording decorative motifs carried out on their handiwork. The lines of the design are drawn on a metal plate, usually copper, with a sharp triangular chisel-like tool called the **graver** or **burin**. The edge of metal turned up as the tool is pushed forward is polished off to leave a smooth surface except for the graven lines. These lines receive the ink which moist paper soaks up in the press to produce the print. It is a linear process; tone and intermediate values can be obtained by flecking or dotting the area with little holes; or by use of fine parallel or crossed lines. Great pressure is necessary and the edge of the plate leaves a mark known as the **plate line.** The quality of an engraving lies in the clear clean line well controlled. Used with mastery in Italy and Germany since the 16th cent. engraving was revived in France in the 18th cent., principally for portraits. Today it is used principally by English artists.

**Etching.** This process resembles engraving in being linear for both outline and tone effects, but the lines are eaten into the metal plate (most frequently copper, though zinc and iron are used) by acid instead of being cut directly with a tool. The design to be printed is traced, with a needle, through a layer of varnish or wax ground impervious to acid, down to the metal. These bared lines are eaten out on the plate by the corrosive action of a solution of nitric acid. The depth and size of the lines are controlled by the successive immersions in the acid bath. The lines to be lightly "bitten" are covered almost immediately with varnish; those to be deep and heavy are bitten more thoroughly. The acid-etched lines hold the ink, which is forced out in printing by the press at great pressure. As in all intaglio processes a "plate line" results. Additional tone effects can be obtained in printing by leaving a thin coating of ink upon the surface or portions of the plate each time it is run through the press, a procedure known as **wiping.** The quality of the line also may be manipulated to a degree by careful pulling of the ink out of the lines with a cloth (**retroussage**) at each printing. Developed in the 17th cent., notably by Anthony Van Dyck and Rembrandt, etching has been popular ever since. It was especially effectively used by English artists and the American Whistler in the 19th cent., and is popular today in Europe and America. The quality of an etching depends on the freedom of line and the varied and rich effects obtainable. It is often used in combination with aquatint, and sometimes with dry point.

**Soft ground etching.** Another etching process, though of less frequent use than the foregoing, is soft ground etching, which somewhat resembles in effect a pencil or soft crayon drawing. It is done by using a soft varnish or ground. A paper is then placed over the surface and a pencil drawing made. The pressure of the pencil forces the soft varnish to adhere to the paper, leaving lines, closely approximating those of the original pencil, bared to the surface of the metal which is then immersed in the acid bath and biting takes place as for a line etching.

**Aquatint.** As in etching, the design is eaten into the plate with acid. Aquatint, however, depends on tonal areas instead of line. The varnish or ground used to cover the metal plate is granular, usually fine rosin grains thickly sprinkled over the plate, which permits the acid to eat through the minute intervals between each grain. Successively, areas to be left white (**unprinted**) are blocked out with the regular stopping out varnish, lightly toned areas are immersed briefly, then stopped out, and so on with each part of the design until the darkest areas are reached which are velvety black in printing because the little pits eaten by the acid during the many immersions are deep and close together. Linear effects may also be added by the usual etching process or by drypoint. Aquatints, like wash drawings, build up their forms by tonal gradations and their quality is dependent on the manner in which the rich range of values from the white of the paper to the black of the most heavily bitten areas

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

is used. Especially popular in the 19th cent., it remains a much used process today.

**Stipple engraving.** Used often in connection with etched processes, this method of producing tone depends on piercing the varnish ground with a multiplicity of small dots, and further adding dots or flecks directly on the plate with the special stipple engraver.

**Drypoint.** A process used for its own sake, but also to add richness of effect to etching, consists of scratching directly on the copper plate with a sharp-pointed needle. The thickness of the lines depends on the amount of pressure used by the artist, but the rough edge of the furrowed line is not removed as it is in engraving. In this case the little **burr** of metal turned up by the furrowing of the tool as well as the line beside it holds the ink in printing, and produces a surface richness on the print in which the ink appears to stand out in relief. As soon as the burr wears down, as it does very quickly, this effect is lost, so that the number of prints from a plate is limited. Sometimes the plate is plated with a thin steel facing for greater durability.

**Mezzotint.** This process gives effects of tone in mass. The copper plate is uniformly roughened or scored with a **roulette** or **rocker** so that it would print when inked an intense uniform velvety black. The design is then worked out by polishing the plate to a shiny hard surface that will not retain ink for the highlights, which are to remain of the white of the paper. The areas of intermediate tones are polished down (**burnished**) also according to their value, between the black of the plate and the polished surface of the highlight, so that all intermediate tones are obtained by removing more or less of the roughened copper surface of the plate with a **scraper** or **burnisher.** The mezzotint was much used in the 18th cent. to reproduce paintings. It is too laborious a process to have much attraction for the creative artist and has rarely been used since, or for purely creative work. In mezzotint, as for all the other processes described above using metal plates, printing is done in a press under great pressure and the plate line always shows.

All these intaglio processes can be adapted to color printing by using a number of plates, carefully keyed to print exactly one over another, each one taking care of the portions of the design in a given color. Mezzotints, etchings, and engravings in color were much used in England in the 18th and early 19th cent., in sporting and horse racing prints, and in the reproduction of famous paintings by the popular painters of the day.

**Lithography.** This method was discovered by Aloys Senefelder in the late 18th cent. It produces the most autographic of prints for it offers the artist the most freedom and directness in transcribing his design, and reproduces it with great fidelity. Lithography is in part a chemical process, and is based on the principle that oil and water do not mix. The drawing is made with greasy crayon or ink upon a special type of stone as freely as if the artist were drawing on paper. By the application of gum and nitric acid the grease is driven into the stone and "fixed". This portion always thereafter attracts the greasy printer's ink rolled over it, while all other portions of the stone's surface are protected by the water which will not cover the greasy drawing. A greasy ink or wash may be used to make the drawing and the resulting print somewhat resembles in effect a wash or ink drawing and may be called a **lithotint.** It is possible to do lithography on an aluminum plate, and commercially, other materials, like a rubber mat, are used. Drawings may also be made on especially prepared paper in greasy crayon and then by pressure transferred to the stone. Best contemporary practice favors working directly on the stone. Lithographs are printed by considerable pressure in a press, but no plate line results. Lithography was much used in the 19th cent. for illustrations, and it has many important modern commercial applications. It is a favorite print medium with contemporary artists, because of its infinite possibilities and its directness and flexibility, which give full scope to personal expression and style. Technically its great qualities are its richness of effects with strong contrast of deep black to white of paper, the infinite gradation of intermediate grays between these extremes, and the wide range of texture and effect possible. By multiple stones, each carrying a different color, and keyed for perfect register, color lithographs are produced, and have had some use as a creative art medium, while elaborate developments in the commercial field are commonplace.

**Color print.** As indicated above, each of the standard print processes can be adapted to color printing, by the use of multiple plates or blocks, each for its own color, keyed to print exactly in register, and used successively. However, except for the Japanese print which can be said to exist only as color print, and the chiaroscuro which depended

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

essentially on several areas of usually neutral tone, the print mediums already described are most important as an art medium in black and white. Color had been added by hand to prints from the earliest woodcuts, and some hand coloring was usually added to color prints in 18th cent. England and France as an addition to the printing in color. The contemporary development of a process for multiple production of designs used primarily for color work has depended principally upon refinement of stencil techniques. In its simplest form this technique consists of breaking a design to be reproduced into areas of different colors which are cut out of cards, which are then keyed like printing blocks, and applied one over another, the respective colors being pushed or squeezed on the paper through the holes left for the purpose. It is a somewhat slow process, and best adapted to decorative designs, dependent on flat areas of color for their effect. A more flexible and easily handled variant of the stencil print, like it first used commercially, but within the past four or five years mastered by a large number of artists in the United States as a creative art medium is the serigraph or silk screen print.

**Serigraph or silk screen print.** Used first commercially, this process was the subject of extensive experiment by artists under W. P. A. direction from about 1936, and has finally become in the hands of some experts a most flexible, expressive and varied creative medium in color, which permits a multiplication of examples and the resulting relatively low price which has always been the advantage of the print as compared with other art forms. A frame on which very fine silk mesh (or screen of other material is possible) is mounted and after mounting is placed over the paper to be printed. The design is worked out in a type of varnish which is impervious to the ink and stops out those portions not to be printed. A special ink or paint is then passed over the frame and penetrates to the paper below through those areas on the mesh unstopped out by the varnish. The drawing in varnish can be removed and the screen used again, for other portions of the design in other colors, or for other designs, as the case may be. As in other color print processes the printing must, of course, be repeated for each color, but technique and apparatus required are comparatively simple. A large group of artists in the United States are now practicing this technique with notable success, and have made of it an independent creative medium of the most varied range, technically and expressively.

**Monotype.** A unique print, produced by painting on a glass or metal plate or other surface and transferring the design in color by pressure to paper, monotype is not strictly speaking a print in the sense of the others described here. As a process it dates from the 19th cent. and has considerable use among contemporary artists.

In all prints the combination of the artists' creative ability and of the technical execution is of greatest importance. In some periods, the artist has furnished the design, and artisans and craftsmen have executed it in one or another medium. In modern practice artists generally prefer to carry out the mechanical as well as the creative portions of the work themselves on the theory that only by direct knowledge of the entire process can they have the full understanding of the medium and its use and possibilities. It is true that in each step of a print-making process there are opportunities for triumph or failure. Ideally, the original design used by the artist to express himself should be fine and adapted to the print process which he chooses for it. In applying it on the block or plate or stencil he should use every resource of the process appropriate to expressing his design. In printing, the inking, the paper, the pressure all may make or mar the print even if all preceding steps have been successful. Because of their multiplicity prints have always been comparatively inexpensive, and today as in Dürer's and Rembrandt's time are an art form available to the mass of the people. It is appropriate that in our time color in a freer, richer, more creative use has been added to the resources of the multiplied original work of art, to satisfy the greater taste for color and interest in it which are the heritage of modern painting.

TECHNICAL TERMS. For a complete explanation of technical terms, see Hind, pp. 1-17, and Kistler, pp. 200-205, etc. A few important terms used in connection with prints: **Edition**, the number of prints, issued, often numbered by contemporary artists, with total number printed indicated, as 3/50, 3rd of an edition of 50. **Impression**, each print produced. **Proof or trial proof**, impressions printed while the artist is working on the block or plate to check progress. **State**, when, as occasionally happens, the artist prints a number of impressions, changes the plate and

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

prints others, the first group are said to be of the *first state,* those printed later after the addition or revision, of the *second state,* etc. **Remarque,** a sketch originally made by the artist on the margin of his plate to test his tools. In the 19th cent. such sketches came to be valued as a part of the finished print but they are not used on prints today. **Steel facing,** a thin layer or plating of steel that may be added to metal print plates for greater durability, often used for drypoint (q.v.), to assure an edition of good quality larger than the untreated plate would give. See Hind, Arthur, M., *A History of Engraving and Etching,* 1923; Kistler, Aline, *Understanding Prints,* 1936; Leighton, Clare, *Wood Engraving and Woodcuts,* 1932; Morrow, B. F., *The Art of Aquatint,* 1935; Reichel, Anton, *Die Clair-obscurschnitte des XIV., XVII., und XVIII. Jahrhunderts,* 1926; Von Seidlitz, Waldemar, *Geschichte des Japanischen Farbenholzschnitts,* 1897, 1910, 1920; Sternberg, Harry, *Silk Screen Color Printing,* 1942; Wegenroth, Stow, *Making a Lithograph,* 1936. —G.L.M.M.

**prints, Japanese.** For terms, see the following: *beni; beni-e; beni-zuri-e;* broadsheet; *chūban; dai-bon; diptych; e-hon; hashira-e; hoso-e; ichi-mae-e; kakemono-e;* keyblock; *kira-e; koban;* lacquer print; *nima tsuzuki; ninshō; nishiki-e; ōban;* pentatych; pillar *sammai tsuzuki; surimono; tan; tan-e;* triptych; wood block; wood-block print; *yoko-e;* also *Modern Japanese Prints,* The Toledo Museum of Art, 1930 and 1936; *Japanese Colour Prints,* Edward F. Strange, Victoria and Albert Museum, 1923; *Block Printing and Book Illustration in Japan,* Louise Norton Brown, 1924; *Japanese Colour Prints,* Laurence Binyon and J. J. O'Brien Sexton, 1923; *Subjects Portrayed in Japanese Colour Prints,* Basil Stewart, 1922; *Japanese Woodblock Printing,* Hiroshi Yoshida, 1939; *The Ukiyo-e Primitives,* Yone Noguchi, Privately Published, 1933; *A History of Japanese Colour-Prints,* William von Seidlitz, 1910; *Chats on Japanese Prints,* Arthur Davison Ficke. —J.A.M.

**private collector.** See FORGERIES IN PAINTINGS.

**privately issued, printed.** *Book.* It is believed that the term is not legally defined, but is usually understood to mean a book all the copies of which are subscribed for, without being offered to the public, before printing and none sold after printing. —H.E.S.

**producer.** See RADIO DRAMA.

**progression.** *Mus.* The movement from one chord to another.

**prolation.** See NOTATION.

**pronaos.** See HELLENIC ART.

**proof.** *Book.* (1) The full-sized leaves of a book not cut when the rest of the book is cut to show the amount of margin that has been cut. (2) Proof copies in binding are those bound from the sheets printed in proof, to submit to the author, publisher, ect. Also proofs of type matter used for checking or "proofreading" for accuracy of composition. See PRINTS AND PRINT PROCESSES. —H.E.S.

**proof before letter.** In engraving and etching, a proof impression taken before the title or inscription is engraved.

**prop.** See STAGESETTING.

**proper.** See HERALDRY.

**Proper, of the Mass.** See Mass; MEDIEVAL MUSIC.

**proportion.** This term is used in literary criticism in a sense generically similar to that of *balance* (q.v.), but is customarily restricted in application to the artist's treatment of his subject-matter. An artist—and hence, his work—is said to exhibit *proportion* when he respects and adheres to the true worth and significance of the different elements of his subject, and gives to the various aspects of this subject the emphasis that they deserve. The use of the term thus involves an assumption about comparative values in the real world, and works are praised or condemned by this criterion as they make agreeable or disagreeable judgments concerning the relative importance of these values. —I.J.

**proportional divider.** See compass.

**proscenium.** See STAGESETTING.

**prose.** See MEDIEVAL MUSIC.

**prosody.** The science of metre, or metrics.

**proto-Attic, — Corinthian, — Doric, — geometric.** See HELLENISTIC ART.

**proto-Renaissance.** See Hohenstaufen art.

**provenence.** See FORGERIES IN PAINTING.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**Provincial French style.** See FURNITURE.

**Prussian blue.** The first blue pigment to be made synthetically on a large scale, this was first produced in the early years of the 18th cent. by Diebach, a dryer or color maker of Berlin. It is also called Berlin blue, Paris blue, Antwerp blue, and Chinese blue. Chemically it is complex but can be described as a ferric ferrocyanide. It is usually made by a precipitation process. Because it can be given an approximate date for entry into the arts, the analytical identification of Prussian blue has frequently been the means of placing a limiting date on picture in which it has been used. —G.L.S.

**psalm tones.** Eight formulas corresponding to the eight modes to which psalms are chanted. Occasionally the *Tonus peregrinus* (strange or foreign) is employed. A Roman numeral at the beginning of its antiphon indicates the psalm tone to be used (see psalmody). The psalm tones are given in pp. 113-117 of the *Liber Usualis*. For a detailed exposition of the manner in which texts are fitted to tones see Rev. Dom. Johner, *A New School of Gregorian Chant*, pp. 65-93, 1925. —V.A.

**psalmody.** The three forms of psalmody, each having its own method of delivery are (1) the responsorial psalmody, (2) the antiphonal psalmody, and (3) the direct psalmody.

(1) **Responsorial psalmody**, the oldest of these forms was taken over from the Synagogue. It was practiced in the early days of the Christian Church as follows: The psalm was chanted by a soloist in a monotone with inflections and cadences at appropriate places in the verses. At the close of each verse the congregation interjected a response—hence responsorial psalmody. Out of this primitive procedure grew the more or less elaborate type of responsorial chant in the Mass and the Divine Service. Even the most elaborate psalmody of this character clearly shows its origin, and can be analyzed on the three-fold basis of intonation, inflected monotone, and cadence.

(2) In **antiphonal psalmody**, two choirs or groups chant alternately. The structure of the psalms naturally led to this manner of chanting which also originated in the Synagogue Service. Ignatius of Antioch (d. 115) is supposed to have introduced the antiphonal method into Christian worship after having seen a vision of angels singing in alternate choirs. St. Ambrose (c. 340-97), Bishop of Milan, is credited for its introduction in the west. In the early days, a refrain or *antiphon* introduced the psalm and was repeated after each verse. Later (c. 9th cent.) in the interests of brevity the antiphon was sung at the beginning of the psalm and repeated only after the concluding *Gloria Patri* (see doxology). The antiphonal psalmody of the Office is less elaborate than that of the Mass. Although technically the Introit, Communion and in a certain sense the Offertory of the Proper of the Mass are antiphons, the word is now used to indicate the psalmody of the Breviary Offices sung in the antiphonal manner.

(3) In **direct psalmody** (*in directum*) which survives in the *Tract*, the verses of the psalms are sung without any refrain, i.e., sung from one end to the other. See Psalm tones; MEDIEVAL MUSIC; also Article, *psalmody* in Grove's *Dictionary of Music and Musicians*, 1935. —V.A.

**psaltery.** See MUSICAL INSTRUMENTS.

**psychological aesthetics.** See AESTHETIC INQUIRY, CURRENT TYPES OF.

**PSYCHOLOGY OF ART.** Psychological investigations in the realm of art have developed along two main lines, one general and the other specific. The general line includes studies and views on the nature of the creative process and the creative mind, and the nature of the aesthetic experience. The specific line consists of efforts to bring art into the sphere of experimental science.

*The nature of the creative activity.* It is in the main agreed upon by students of what goes on in the mind of the creative worker that the creative idea is the result of a long mental process divisible into the steps of *preparation, incubation, illumination,* and *verification.* In preparation the seed for the creative idea is planted in the soil of creative mindedness, whether consciously or unconsciously; in incubation it undergoes development until it sprouts and flowers forth in illumination, and matures and is harvested in verification.

There is also considerable agreement that what characterizes the creative mentality, as compared with ordinary practical intelligence, is a high degree of susceptibility for experience, an overwhelming inner power, and an irresistible drive for expression. Genius is said to possess, in the words of Bergson,

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

"un élan, une initiative, une effort pour faire produire a la matière quelque chose que, d'elle même, elle ne produirait pas". This happens because of the great significance that the stuff of experience possesses for a richly endowed mind, a mind which is, so to speak, pitched an octave above that of the ordinary person. This accounts for the originality of the work of genius as compared with that of talent. The creations of genius are rooted in nature and life, while those of talent are either imitations of, or departures from, older masters.

These views on the creative process and the creative mentality find full corroboration in what creative workers with a bent for psychological introspection and analysis report about their mental adventures, and in studies on the genesis of particular art masterpieces. An example of the former is the account given by the French mathematician Poincaré of the origin of his mathematical formulas, and an illustration of the latter is Lowes's exhaustive study of the sources of Coleridge's *Kubla Khan* and The Ancient Mariner. Poincaré speaks of the appearance of a sudden illumination as a manifest sign of long, unconscious prior work. The sudden inspirations appear only after days of conscious effort which seemed quite fruitless. It is this effort, however, that set the unconscious machine agoing, and without which nothing could have been produced.

Lowe's study of the two poems by Coleridge leads him to the conclusion that "Every great imaginative conception is a vortex into which everything under the sun may be swept . . . Oral traditions—homely, fantastic, barbaric, disconnected—which had ebbed and flowed across the planet in its unlettered days, were gathered up into that marvel of constructive genius, the plot of the *Odyssey,* and out of 'a tissue of old Marchen' was fashioned a unity palpable as flesh and blood and universal as the sun itself" (4, p. 55).

*The nature of the experience of beauty.* The outstanding feature in the development of theories regarding the nature of aesthetic experience is the increasing recognition that what appear to be contradictions are in some instances but differences in manner of statement rather than in matter stated, and in other cases the apparent disagreements arise from the fact that each theory stresses one out of three possible approaches to a complex experience. Thus, some theories concern themselves with the nature of the experience itself, others with what the experience is experience of, and some with what the experience does to the experient. To the first class belong the theories of *intrinsicality, disinterestedness,* and *objectification;* to the second the theories of *significant form* and *intuition;* and to the third those of *psychical distance, aesthetic repose,* and *catharsis.*

Disinterestedness, intrinsicality, and objectification belong together, because a disinterested attitude gives rise to an intrinsic experience, and in an intrinsic experience the subjective is objectified. The theories of significant form and intuition come to the same thing, each calling attention to what it is that is experienced in beauty. Bell defines significant form as the common quality in all visual art, and this common quality lies in certain forms and relations of forms that stir the aesthetic emotion. Croce contrasts intuition with intellect by calling intuition the process by which we obtain knowledge of individual things, while intellect gives knowledge of relations between things.

Of the third group of theories that of catharsis is the oldest and most widely known. Aristotle states in the *Poetics* that it is the service of tragedy to effect a proper catharsis or purgation of the emotions of pity and fear, and attributes such an effect also to music in the *Politics.* Now whereas Aristotle nowhere explains directly the nature of this purgation, we can infer what he had in mind from his definition of fear in the Rhetoric as "a species of pain or disturbance issuing from an impression of impending evil which is destructive or painful in its nature". It is clear, from this definition, that a catharsis of fear must consist of the elimination from it of the "impression of impending evil", in which case the fear becomes, in the words of Butcher, "an almost impersonal emotion, attaching itself not to this or that particular incident, as to the general course of action which is for us an image of human destiny" (4, p. 146). In other words, the emotion is stripped in imagination of its biological implications and becomes intrinsic experience. In such case, the restlessness, the drive to action, that is the dominant trait of every-day emotion, also disappears, resulting in a state of repose in tension. And this is Puffer's definition of beauty as aesthetic repose. Bullough's theory of psychical distance states the same thing in different language. If a person is psychically distanced from himself when standing on a hillside with lightning playing about him he is at repose because he is engrossed in the phenomena rather than

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

in the thought of the danger to himself. Psychical distance is but another name for catharsis, only it explains how the catharsis is effected.

*Experimental aesthetics.* The most fruitful definition of experimental aesthetics is offered by Munro as "making use of all possible clues to the nature of aesthetic experience, from a variety of sources and modes of investigation. It would imply putting all these clues together, and on that basis working toward tentative generalizations through induction and the testing of hypotheses" (3, p. 24). A considerable literature on art that fits into this conception of experimental aesthetics has accumulated since the first researches were conducted along this line by Fechner (1865). We can do no more here than enumerate the main problems that have been investigated in each of the arts.

*Visual Forms.* Fechner's purpose was to determine experimentally the degree of pleasantness of a series of simple visual forms constructed by himself, as well as of existing objects whose proportions were obviously influenced by aesthetic considerations. This procedure was also followed by Witmer (1893), Augier (1903), Legowski (1908), Thorndike (1917), and others. Chandler summarizes the results of these experiments as follows:

"Fechner had begun experimentation with simple forms in the hope of determining the one best form in each category—the best rectangle, the best cross, etc.—at least for any group homogeneous as to race, culture, and maturity. The results reached by his successors failed to show any one best form in each category; individual differences became conspicuous; the irrelevance of exact ratios like the golden section became evident; only such vague criteria as moderation, simplicity, or comprehensibility retained any validity" (1, p. 44).

Similar studies have been made by numerous investigators on the pleasantness of colors, singly and in pairs, the results showing no substantial agreement either among the subjects used in the different experiments or in the conclusions reached by the investigators.

The results of investigations on the expressiveness of lines and colors show a modicum of uniformity. Thus, big curves, downward or horizontal, are quite consistently judged to be sad, lazy, serious, weak, dead, quiet, gentle; small curves, and at times angles, upward and horizontal, are playful, merry, agitating, furious and hard. For the effect of colors it can be said that not every effect is likely to arise from every color equally, as, for instance, saturated reds are not cold, nor are the darkest colors cheerful.

*Auditory forms.* The experimental literature on music is vast and varied, comprising studies on its effects on animals and human beings, the classification of listeners into types, the nature of the beautiful in music, and the psychology of melody and harmony.

*The Effects of music.* There are numerous studies on the physiological, emotional, and mental effects of music, from single tones to complete compositions, and the feeling effects of the elements of melody, harmony, rhythm and tempo. The data from these studies indicate quite conclusively (1) that the effects of music on organic processes are quite pronounced; (2) that emotionally music creates a mood rather than specific feelings; (3) that a musical composition tends to create a uniform mood in an audience; (4) hat the intellectual effects of music vary from person to person; (5) that the most important melodic element for the expression of excitement is swift tempo; for dignity it is slow tempo, firm rhythm and lower pitches; dreamy sentimental moods call for the minor mode, slow tempo and flowing rhythm; while happiness demands faster tempo, simple harmonies, flowing rhythm and medium pitch.

*The types of musical responses.* Experimental data point to four classes of listeners to music. These are the *intra-subjective* type, to whom music appeals for its sensory, emotional, or conative effects; the *associative* type, which values music for the associations a critical attitude towards music and values it as an object; the *character* type, which characterizes music in terms of human traits like morbid, joyful, mystic, etc. These four types are further reducible to two classes of listeners based upon the source of the meaning of the music to the person. There are those who value music *intrinsically,* or for the music itself, and those who prize it *extrinsically,* or for the extra-musical message it conveys to them. There are grounds for believing that the intrinsic listeners are the truly musical persons.

*The aesthetic hearing of music and the traits of the musical mentality.* Inquiries among outstanding musicians and laymen with pronounced interest in music justify the conclusion that music is heard musically only when it is heard through and through tonally. These persons report that whenever anything it arouses; the *objective* type, which assumes

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

extra-tonal intrudes into their consciousness while listening to music, it is an indication that the music no longer interests them or that it is trivial music. A battery of tests of auditory sensitivity and discrimination administered to these persons shows that they rank above average in these abilities, from which it may be inferred that at the basis of the aesthetic response to music is a high degree of sensitivity to the structural elements of music like pitch, dynamics, duration, tone quality, interval discrimination, tonal movement, and many others.

*The psychology of successive tonal combinations.* Since a melody is a succession of pitches that are experienced as an organic whole, many students have inquired into the sources of this phenomenon of tonal belonging-togetherness. Ortmann enumerates three *absolute* and five *relative* factors which account for the tonal relationships in a melody. The absolute factors are *first and last tones, highest and lowest tones,* and *tone repetition;* the relative factors include *interval, pitch direction, pitch proximity, emphasis in tone-groups,* and *interval relationship.* The first and last tones and the highest and lowest tones give the melody its temporal and pitch boundaries, and thereby become a source of unity, while tone repetition serves the same purpose through frequency of stimulation. The five relative factors serve to unite the tones through contiguity in time and pitch. Bingham investigated the phenomenon of melodic trend or finality and formulated the law that *"two melodically 'related' tones tend to establish a tonality,* and the melody is judged to end only when the final tone is one of the members of the tonic triad—preferable the tonic itself" (5, p. 42).

*The psychology of simultaneous tonal combinations.* A number of theories have been formulated in explanation of the fact that the intervals of the musical scale differ in degree of consonance and dissonance. The most prominent of these theories explains consonance as degree of fusion (Stumpf, 1898), and fusion is defined as the singleness of impression produced by two or more tones. The greater the fusion the greater is the consonance of the component tones. The upholders of this theory do not agree, however ,on the basis of fusion. Some hold that it depends upon vibration ratio of the tones, while others claim that numerous factors are operative. Consonance has also been accounted for on the basis of the beats of the upper partials (Helmoltz, 1870), the harmonic series of partials (Ogden, 1920), the chord of nature (Redfield, 1928), cultural acquisition (Moore, 1914).

*Language and Literature.* In the realm of the verbal arts, research studies have been made on the rhythm of speech, the effects of speech sounds, and the effects of single words.

Scripture (1899) sought to determine the nature of the rhythm of verse by analyzing mechanical recordings of spoken verse, tracings on phonograph records, and other devices. He found "accent"to be a combined effect of a number of factors, and not alone of loudness or duration. This combined effect he called "energy" or "strength", and the rhythm of verse he claimed to consist of the periodic recurrence of *regions* of strength and of weakness. The midpoint of a region of strength he named the "centroid", with intervals between centroids being approximately equal. Wallin (1911) calls the interval between centroids a "sound centroid interval" when no pause occurs between the centroids, and a "composite centroid interval" when a pause does intervene. His data show no constant length of interval between centroids. Also, according to his results, loudness is the most prominent factor in accent, with duration next and pitch last. Patterson (1916) corroborates Wallin's view that rhythm is not conditioned upon mathematical regularity of recurrence of centroids, because pulses can be accelerated or retarded, or the interval between pulses can be divided into several shorter intervals, or several intervals combined into one longer interval, or the interval may be syncopated. Patterson finds three rhythmic types: the "stresser" or the person whose rhythmic experience is predominantly in terms of alternations of stress or the differences of loudness among the syllables; the "passive timer", or he who responds to the objectively given temporal regularities; and the "active timer", or the individual who sets up subjective time patterns into which he fits the presented stimuli. The difference between prose and verse, according to this investigator, lies in the way of hearing or reading a passage. "For a 'timer,'" he concludes, "the definition of prose as distinguished from verse experience depends upon a predominance of syncopation over coincidence in the coordination of the accented syllables of the text with the measuring pulses" (1, p. 259). In other words, the distinction is subjective, not objective. But Griffith (1929) finds the difference between grades of rhythm

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

in prose and that between the most rhythmic prose and blank verse to reside in the length of pause and the length of phrase in time and in number of syllables. She reports that spaced prose is a structure of many pauses, or comparaticely short phrases balanced against one another—hence spaced. There is a greater difference in the pauses occurring *in* a sentence and at the *end* of a sentence between fluid and non-rhythmic prose than between spaced prose and blank verse. In non-rhythmic prose the pauses are fewer and shorter than in blank verse and spaced prose. The length of phrases as measured by the number of syllables they contain is relatively brief in time for blank verse and spaced prose as compared with other prose. Also, 75 per cent of the phrases in blank verse contain even numbers of syllables, while all three forms of prose predominate in phrases of odd numbers of syllables. Further, the most frequently occurring phrases found in blank verse contain four and six syllables, in spaced and fluid prose this happens with phrases of five and seven syllables, while in non-rhythmic prose there is no predominance of any particular phrase lengths. Finally there occurs a steady increase in the duration of the phrase with the number of syllables in it, up to ten syllables for blank verse, thirteen for spaced prose, twenty for fluid prose, but for non-rhythmic prose no regular relation is found whether for short or long phrases.

*The feeling effect of speech sounds and words.* From the results of studies on the feeling of speech sounds, there appear to be very slight differences in the degree of pleasantness of the different vowels and consonants. One investigator, however, reports that when the sounds of a poem, especially of a lyric poem, are arranged into nonsense syllables and composed into iambic lines, the sounds themselves are able to arouse a mood somewhat like the mood of the original poem.

The investigations on the effects of single words have led to a four-fold classification of responses similar to that found for tones and colors.

*Sculpture and Architecture.* To the knowledge of this writer no experimental studies on these arts are available at present.

**PSYCHOLOGY OF DRAWING AND PAINTING.** This article deals esp. with the processes of perception and visualization involved in the acts of drawing and painting as modes of realistic representation. Research in the psychology of the production of art is still in an early stage of development, and quantitative information on much of the following discussion has not yet been published: but no positive statements are made here which are not well substantiated by at least qualitative evidence.

PSYCHOLOGY OF FORESHORTENING AND LINEAR PERSPECTIVE. From the standpoint of *perspective* (q.v.), a picture is essentially a two-dimensional projection of three-dimensional material. If two untrained people of equal moderate ability draw a greatly foreshortened view of a long table top, A, tracing its image as it appears to him on a perpendicular pane of glass, will draw it correctly, while B, drawing on paper in the ordinary way, will make the distant and near edges too far apart. B, lacking a tangible *picture plane* for the gathering of his visual images, is unable to relate them properly; his judgment of proportions in them is influenced by his perception of the real length of the table. The new vision of adults who, born blind, have been given sight by surgical operation, is practicaliy flat, like a picture, all objects seeming to be about equally near; and it is only after considerable experience in handling objects and moving around among them that these patients acquire normal visual perceptions of distance, size, and foreshortened form. This experience is gained by most people in early infancy; and the primitive consciousness of visual images as such has been so long neglected by the time an individuai begins to draw intelligibly that he is hardly aware of them. An important part of the teaching of drawing is the reawakening of a consciousness of these visual sensations. A well-trained artist is able at will to think clearly and accurately of an object either *visually,* in terms of a flat or spherical pattern of images, or *constructively,* in terms of concepts of the real object, of three-dimensional space rela-

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

tionships. A less trained person drawing usually mixes those two types of thinking without realizing that he is doing so. This is the principal explanation of the traditional difficulties of foreshortening, which have troubled artists of all times, causing ancient or primitive artists to represent for instance people with shoulders in front view while heads and feet were in profile view.

The normal tendency to think of the objective real instead of the subjective sensation is called **constancy**, or **phenomenal regression**, which terms are applied to judgments of size, form and color. (The last will be discussed later).

The difficulties already mentioned arise from a confused mixing of constructional concepts with what should be, under some circumstances at least, practically pure visual images. Conversely there is a different kind of trouble that comes when visual thinking intrudes too much upon what should be mainly constructional thinking. This is illustrated by Hogarth's famous jocular drawing which shows a man on a distant hill lighting his pipe from a candle held out by a woman from an upper window of a nearby house. While no sane person ever commits so glaring an absurdity unknowingly, art students often make mistakes which though somewhat disguised are the same in principle—assuming parts to be near each other in space because they happen to be juxtaposed in the drawing, when they really belong in different planes of depth. This type of error which commonly occurs in drawings from imagination is essentially identical with another form in which adjacent parts of an object are individually drawn well but their intersections or other interrelationships are not thought out properly—as, for example, when a beamed ceiling is drawn without regard for the shapes made by the beams in penetrating the wall. All such faults appear to come from *incomplete visualization*. The student is able to conceive separately of the beams and of the wall but does not exert enough imaginative effort to bring into clear focus, as it were, the junction between them. The man and the woman, in the previous type case, are both clearly realized, but the ground between them is forgotten.

EXCESSIVE CONCENTRATION OF ATTENTION. Even when a drawing is being made from an observed model the relations between parts are frequently neglected. As has been indicated before, a drawing on paper from observation involves more than a mechanical matching of the visual images received from it with those received from the model. Many influences come into play and modify the mental impressions made by the images. Among these *attention* is important. Any part of the object which is especially interesting tends to receive special attention, to the neglect of other parts. The result usually is that the former is refined increasingly; more and more minute details are added, space for which is robbed from the surrounding areas, with the result that the interesting part is made too large, if the drawing is of moderate size. If the drawing is unusually large in scale, however, the part is likely to be made too small. In either case the same cause is operating—too narrow a confinement of attention.

ARBITRARY SPACE UNITS. A remedy for this difficulty is a special effort to pay attention to the shapes of the comparatively empty, uninteresting areas that surround these centers of spontaneous interest. In fact it is important to go further and to conceive the whole drawing as composed of arbitrary visual units of abstract space or masses which are largely independent of constructional units. For example, suppose a model is seated with an elbow on a table, leaning his head on his hand. One mass might be thought of as bounded by the outer edges of the head, hand, arm, part of the edge of the table, part of the edge of a shadow which chances to fall across the body, a fold in the sleeve of the other arm, a part of the back and the edge of the neck—all combining to make an imaginary approximation to a triangle. Another mass might be conceived that omits the head but includes the knees and parts of the chair. There is great advantage in thus making units of space overlap each other, having elements in common which are used again and again in many varied relationships, like parts of letters in a monogram, since each mode of thinking about a given component thus serves as a check on the other modes; and mistakes of proportion are discovered which would otherwise escape notice. As this work proceeds, the units become gradually subdivided into smaller and smaller sub-units, until all important relationships and areas are properly adjusted, a proof of correct proportion in the larger masses being the ability of the smaller subdivisions to fit into them rightly. Considerations of structure, anatomy, and perspective furnish additional proofs; but, though important, they must needs be secondary to consideration of visual pattern if truthful representation of a specific model

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

and pose is desired, since an infinite variety of forms can be satisfactory from the structural, anatomical or perspective standpoints while only one set of forms can represent the visual patterns of that particular arrangement. Therefore the establishing of habits of thinking in terms of arbitrary space units is one of the chief objectives in the teaching of drawing.

EXAGGERATION OF SLIGHT DIFFERENCES. Another problem concerning attention arises from the fact that it is naturally attracted to differences of direction in contours, which if slight, usually are exaggerated. Very obtuse angles tend to be drawn too acute, very gentle curves to be made more rounding, very small irregularities to be augmented. Likewise contrasts of *value*, *hue* and *chroma* (q.v.), occurring in adjacent areas, tend to be exaggerated. For example, a patch of reflected light slightly illuminating the shaded side of an object is frequently made by beginners as brilliant as much of the lighted side, and a half-tone on the lighted side as dark as a shadow.

NORMALIZING TENDENCY. However, there is an opposite tendency which is manifested in cases where the model is extreme in angularity or eccentricity and which tends to make the copy somewhat more conservative, generalized, compact, and symmetrical in shape than its original. Thus these two complimentary tendencies, one toward accentuation, the other toward moderation, in combination help to keep drawings from extremes of simplicity on the one hand or of irregularity on the other. The "Gestalt" school of psychologists advance as explanation of these facts the theory that there is a "law of pregnance" which causes each form as apprehended by the mind to gravitate toward the character of a "good figure" or good example of that type of form. One writer has proposed the name "eidotropic tendency" for this trend of perception toward an ideal for each form.

There is a similar generalizing tendency in the observation of color which tends to cause untrained people to paint in pictures approximations to "local" colors of objects (the colors of a part of an object which is fully exposed to strong but diffused daylight) when they should paint the apparent "stimulus" colors (the modifications of the local color which are due to aerial perspective or to the character of the direct or reflected illumination), probably because the local colors are more typical, more often seen under average conditions. The terms "constancy" and "phenomenal regression" are applied also to this tendency.

The relation of these accentuating and minimizing tendencies to aesthetic preference has not yet been determined experimentally, but there is considerable likelihood that there is a relationship.

EFFECTS OF OPTICAL ILLUSIONS. There are too many *optical illusions* (q.v.) in almost everything we see that there is no hope of entirely escaping from their influence while drawing or painting. However, if realistic representation is desired it is reassuring to reflect that the more closely a picture is made to resemble the appearance of nature the more nearly its particular combination of illusions will come to matching the corresponding illusions in the scene depicted, and hence, the more completely the two sets of illusions will come to neutralizing each other. For this reason if maximum correctness is important it seems desirable that all areas of the paper or canvas be made to vaguely resemble the general appearance of the scene as soon as possible, then be slowly brought into focus, as it were, by a gradual sharpening of edges as the adjustments of masses make locations more certain. A model with strongly contrasting lights and darks, for instance, should be drawn or painted with approximately corresponding value relationships, beginning at a very early stage in the development of the picture, not in outline. If an outline drawing is wanted as a final result, the best procedure, from a psychological standpoint, would be to make a preliminary study in values, then derive the outline drawing from that. A similar plan can be followed in cases where a medium is used which does not lend itself to a gradually focussing treatment. Frequently the backgrounds of models are dark, perhaps complicated with forms of furniture or architecture, while the drawings of them are made with plain white paper as background; or sometimes part of a drawing is given heavy slanting strokes of technique which do not correspond with anything in the real scene. Such departures may be fully justified by aesthetic considerations, but the artist should realize that he is giving himself a psychological handicap, if he desires correct proportions, unless he makes these departures after his study of the proportions has been completed.

LAG OF PERFORMANCE BEHIND JUDGMENT. Suppose a student's vision is misled by certain illusory angles in the model and he makes a certain distance in his drawing too short.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

Even if he later discovers his mistake through neutralizing the illusion by adding the corresponding angles to his drawing, he is likely to fail to make the needed correction, perhaps through lack of energy or of confidence in his own judgment. Errors due to other causes tend to be perpetuated likewise.

The resulting lag of performance behind judgment may be considerably diminished by use of a medium which permits easy alteration, such as charcoal, pastel, or oil paint, and by insistent instructions to keep the drawing vague and simple until all the important masses are correctly adjusted, after which edges can be sharpened, needed details, accents and refinements added, and the result made as clean, crisp and vigorous as may be desired for purposes of aesthetic expression.

Published data on this subject have been thus far largely confined to articles in periodicals and individual chapters in books. Most of these have been summarized in R. S. Woodworth, *Experimental Psychology*, 1938, pp. 71-91, 539-712. —T.I.C.

PSYCHOLOGY OF MUSIC. Throughout the history of aesthetics so many aspects of music have been subjected to psychological study and analysis that no adequate comprehension of the complexity of the field can be given in a brief statement. For purposes of convenience and brevity it is possible to group the various ramifications of the psychology of music under the following four headings:

(1) *The materials of music.* All musical perception begins with the materials of auditory sensation. At the present time a study of auditory sensation overlaps three fields of scientific inquiry: physics, physiology and psychology. Musical sound begins as periodic disturbances of the air which strike the ear drum, and are then transformed by various electro-chemical processes in the auditory mechanism of the ear into a wide range of pitches of varying intensities and tone-colors.

(2) *Musical form.* Auditory sensations become music only after they are grouped into sequences and patterns which vary all the way from the simplest succession of tones in a folk melody to the elaborate structures of modern choral and orchestral composition. Many varieties of musical pattern follow rather strict rules of construction and have acquired a technical nomenclature indicated by such terms as canzona, gigue, fugue, canon, minuet, courante, toccata, passacaglia, chacono, bolero, etc., etc. Psychological studies in this field are concerned primarily with problems relating to the origin of scales, the use and perception of intervals and chords, the degree of auditory complexity to which the ear is adequate, and the analyses of rhythm and harmony.

(3) *Tests of musical talent.* The ability of performers to perceive, discriminate, and execute the materials and forms of music has been subjected to critical analysis in order to construct tests of musical capacity. The best that can be said about these tests at the present time is that they have an important negative value,—that is to say, if a person does poorly on these tests it is not likely that he will succeed as a musician. It can not be said with such assurance, however, that success on these tests will predict success as a musician.

(4) *The meaning of music.* One school of thought in music aesthetics has maintained, ever since the Greeks, that music has no meaning beyond that contained within the auditory structure itself, as contrasted, for example, with arts like painting and poetry which lead the mind into a realm of ideas far transcending the nature of the materials used in the construction of these arts. This formalistic view of music has had a tenacious hold upon aesthetic theory, but has recently been expanded to explain an oft-repeated assertion that music is the language of emotion. Music need not directly arouse emotions in the listener, and it certainly does not contain emotion within its own tonal framework; but its intrinsic tonal structure is nevertheless patterned in such a way that the listener frequently seems to be brought into direct contact with the whole range of human mood and passion. The music itself possesses no passion, nor does the listener himself necessarily feel strong emotion. He listens to tonal configurations which closely resemble in their outline the bodily reverberations which lie at the basis of real emotions. Music sounds the way emotions feel.

The literature on the psychology of music is enormous. The following books may serve merely as examples, and will furnish the interested reader with many references for further study. Haydon, G., *Introduction to Musicology*, 1941; Pratt, C. C., *The Meaning of Music*, 1931; Schoen, M., *The Psychology of Music*, 1940; Seashore, C. E., *Psychology of Music*, 1938; Stevens, S. S., and Davis, H., *Hearing*. 1938. —C.C.P.

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

**psychology of the artist.** See ARTIST, PSYCHOLOGY OF THE.

**psychology of tone.** Psychologically, a single tone is a permanent acoustic impression in which height, intensity and timbre remain more or less constant, the deviation from this constancy being restricted to certain limits and tolerated only if they occur regularly (vibrato, crescendo, articulation). Still, the difference between noise and tone is not principal but gradual.

In comparison with our visual capacities we must admit that a static aural impression is inferior so far as accuracy of location is concerned. It produces more a sensation in us than an image of something eternal, the source of the sound. This holds true even of daily experiences but especially of the use of a tone in music. Thus music with only a static aural impression would be unable to produce a picture. There are only moving-pictures in music. Even localization appears much stronger in motion: approaching, passing by, disappearing.

On the other hand the ear is superior to the eye with regard to the variety of color. The number of possible colors, their discrimination and combination is unlimited. This quality of color does not depend on the wave length as in optics but includes every quality of a sound except its wave length (pitch) and wave height (intensity). Thus *physically* it depends entirely on the shape of the wave and on changes within this shape. These changes account for the deviations mentioned above. They contribute especially to the warmth of a tone. Especially strong at its beginning and ending they produce definite articulation, for singing as well as instrumental rendering. The absence of such changes produces an organ-like character. Every musical instrument is characterized by a specific shape of its tonal wave. *Psychologically* we distinguish: grades of brightness and fullness that depend on the amount of overtones; a kind of vowel character if certain "formant" regions dominate among these overtones; metallic quality if the intensity reduces slowly, and wooden quality if it fades away immediately; light or darkness, smoothness or sharpness, weight, volume and penetrance of a tone. *Musically* these qualities are prescribed by the choice of a certain instrument and the manner of playing it (touch, etc.).

The limits of our capacity to hear extremely high or deep tones is somewhat connected with the limits of intensity since the extreme frequencies are intelligible only at medium loudness and vice versa. The same holds true of the threshold for the distinguishing of very small intervals. The range of audibility reaches from 16 to 16000 oscillations per second and more. For musical purposes, however, the range does not surpass 32 and 4000 oscillations respectively.

Historical and regional styles of music differ in their systems of tones selected for use in music with regard to melodic easiness as well as to the allowance of simultaneous sounding. Yet the natural relationship as given by the harmonic overtones seems to be a fairly general principle for all these systems. The pentatonic scale (d-f-g-a-c) also appears as a very general root for tonal systems throughout the world.

The theoretical fundamentals of the nature of a tone were already known to the ancient Greeks (Pythagoras). Yet the modern scientific research did not start before Helmholtz's historic publication "The Sensation of Tone" (1863). Valuable contributions were added by A. J. Ellis (*History of Musical Pitch*, 1877), C. Stumpf (*Psychology of Tone*, 1883), Th. Lipps, E. c. Hornbostel, M. Wertheimer, E. Kurth, G. Revesz, who more and more transferred the problems from physics and physiology to psychology. The modern invention of electro-acoustics equipped this research with a perfection of tools undreamed of before and promoted abundant results, esp. in the laboratories of the U. S. A.; e.g., The University of Iowa (C. E. Seashore), Carnegie Institute of Technology (M. Schoen), and Peabody Conservatory (O. Ortmann). —H.R.

confused picture of the Eastern Indian cultures, the pueblo culture reveals a clear pattern of continuous evolution from earliest times to the present, and actual dating has been determined in certain areas by dendrochronology (q.v.). The first inhabitants, with the exception of Folsom Man (q.v.), were nomadic hunters and seed gatherers, now called the Basket Makers because of their skill in basketry; and their evolution is divided into Basket Maker I, which is hypothetical, II and III, or, according to other authorities, Basket Maker and Modified Basket Maker. These early nomads wove finely coiled baskets of osier, yucca fiber and roots for household, transportation and burial use, and decorated them with red and black designs of intricate zigzag, terrace and other geometric motifs. Closely allied to basketry was the weaving of bags and sandals of yucca fibers. The sandals in particular show intricate designs similar to those found in the baskets. Both crafts reveal a high quality of craftsmanship. They may be dated c. 500-600 A.D.

The introduction of maize, probably from the south, and later of beans and squash, led to a more sedentary life. The first structures, stone-lined storage pits, assumed a domiciliary function and were given a superstructure of poles and adobe, with a smoke hole for entrance. Pottery was invented or introduced, and decorated with motifs derived from weaving. The Basket Makers seem to have reached their climax in the area drained by the San Juan River.

With the infiltration, beginning c. 400 A.D., of a new race of unknown origin, a transitional age (Pueblo I and II, or Developmental Pueblo, c. 800-950 A.D.) led to the fullest development of the culture (Pueblo III, or Great Pueblo, c. 950-1300 A.D.). Basketry continued, and the use of wild cotton made possible the weaving of cotton cloth, enriched with embroidery. But the two chief arts were architecture and ceramics. The pit house was discarded in favor of one built entirely above ground and evolved into the single-room communal house, yet survived in the subterranean kiva (q.v.). These unit houses of stone and adobe were arranged contiguously in a long row or crescent in widely scattered villages. A trend toward concentration of population led to the building of great terraced communal houses in natural caverns and in the open. Mesa Verde (q.v.) (1073-1262 A.D.) contained one of the greatest groups of the former both as to number and variety of buildings and quality of masonry. Other important sites were the Cañon de Chelly (q.v.) with its many dwellings of various dates, of which the White House (1060-1275 A.D.) is best known; Betatakin (q.v.) (1242-1286 A.D.), Keet Seel (q.v.) (1274-1286 A.D.) and Casa Grande (q.v.) (1300-1400 A.D.). Of pueblos in the open, Chaco Canyon (q.v.) contained large, wealthy villages (at their climax c. 1200 A.D.), composed of communal houses on a rectangular or oval plan, built about a court and terraced back from the one-story rooms enclosing one side of the court to upwards of five stories at the back. Within the court were many large circular kivas with exceptionally fine masonry.

Painting was practiced by the Basket Maker—Pueblo peoples on a large scale, on the smoothed walls of canyons and on boulders. These so-called pictographs or petroglyphs show a great diversity of scale, subject matter and style. They range in size from gigantic to diminutive, depict human, animal and geometric figures, and vary in style from purely geometric to highly conventionalized to naturalistic. Recent excavations have disclosed many mural paintings in the kivas on many successive layers of adobe. At Awatovi, an ancient Hopi village, the designs are highly conventional, reminiscent of Hopi pottery and apparently ceremonial in subject; they are flat and hieratic in style. At Kawaika-a in Arizona and at Kuaua near Albuquerque are represented masked figures, animals and birds in a freer, more naturalistic style.

Pottery consisted first of a black and white ware made possible by the use of slip, with angular textile-like designs; of a unique corrugated ware in which the constructional coils were left unsmoothed (pottery in all the Southwest was coiled, not thrown); and of a polished red ware—all with many shapes for household use, such as shallow food bowls, water jars, cooking pots. Distinctive local styles developed with a trend toward polychromy. Outstanding for their shape and decoration are the Sikyatki (q.v.) bowls with red or brown decorations on a yellow or orange base.

Articles of personal adornment were plentiful—gorgets, necklaces and bracelets of shell and stone and especially of turquoise—and appear to indicate a ceremonial life comparable to that of the historic Pueblos.

For unknown reasons, probably the great drought of 1276-1299 A.D. and pressure from

CC-0. Gurukul Kangri University Haridwar Collection. Digitized by S3 Foundation USA

the invading Utes, Comanches, Navaho and Apaches, the region was abandoned and the people migrated southward, many eventually to the Rio Grande Valley to the sites now occupied by the historic Pueblo peoples. In this period of migration (Pueblo IV or Regressive Pueblo, 1300-1700 A.D.) the culture of Great Pueblo continued, though in decline, until the historic period. In 1540 A.D. came the first contact with Spanish culture, by way of Mexico, and a material change in the pueblo pattern of life through what the Spaniard brought: metal tools: sheep for wool and food; the horse for work and transportation; fruits, vegetables and cereals; and Christianity. Since the Spaniard did not find the gold and other wealth which motivated his expeditions, he did not push his attempts at conquest and colonization until after the rebellion of the Pueblos in 1680 A.D. With the subjugation of the tribes the historic or Pueblo V period (1700 A.D. to date) begins. The large number of villages known to have existed when the Spaniard arrived has dwindled to about 17 in the Rio Grande group. The more important are Acoma, Cochiti, Isleta, Laguna, San Ildefonso, San Juan, Santa Clara, Santo Domingo, Tsia, Taos, Tesuque; the Hopi group (q.v.) in Arizona; and the Zuñi in western New Mexico.

In general the tribes have adapted and profited by some of the material benefits of the foreign culture. Yet they have subordinated them to the long-lived, powerful traditions of their social and religious patterns. There has been a direct continuity of the ancient arts. Building has remained the adobe communal structure, as at Taos; with modifications such as the addition of *portales* and chimneys seen at San Ildefonso.

In all the crafts the influence of the tourist trade has been banal in lowering standards of quality and taste. In the field of weaving basketry has continued, and in the making of woolen articles and cotton garments embroidered in wool a great expansion has taken place. Pottery has always flourished, and each village has developed an individual style, mostly polychrome. It is still a craft of the women. Its enduring vitality has expressed itself in an upsurge from decadence to a revival of ancient quality through the work of several gifted, understanding potters, notably Marie and Julian Martinez of San Ildefonso and Nampeyo of the Hopi First Mesa. Articles for household use and also as *objcts d'art* for trade are produced in great variety.

A recent innovation is the development of a spontaneous contemporary school of watercolor painting by young Indians who are gifted and in their painting free from influence of the whites. The subject matter consists usually of costumed ceremonial figures, alone or in the dance. In style they are flat and decorative, with no backgrounds, and seem to continue the ancient traditions of the art. Important members of the group are Awa Tsira and Crescencio Martinez of San Ildefonso, and Fred Kabotie, a Hopi.

In the field of religion and ceremonial the ancient faith survives with vigor, and the old ceremonials are still enacted in the kivas and on the plazas. Christianity is superimposed upon this faith, and the Indian sees no inconsistency in going to early mass in the Christian church and then performing an ancient religious dance in front of the church in the presence of the statue of the Christian saint.

However, the further encroachments of modern civilization, especially since the development of the West through easy means of transportation and trade, poses the very difficult problem of an inevitable further adjustment. One encouraging aspect is the strong endeavor, on the part of understanding whites who are interested in the preservation of a noble indigenous culture, to assist the artists to maintain the ancient traditions in all their arts and to resist the lowering of quality in the face of quantity demands for tourist trade. **pure drawing.** The essence of drawing with emphasis on the abstract character. See drawing.

**purism.** A movement of secession from cubism, founded in 1916 by Ozenfant and Charles Edouard Jeanneret (later a famous architect under the name of Le Corbusier). Flourishing until about 1925, purism emphasized semi-abstract painting in which faultless precision, clarity, and elegance of line and form, and an impersonal, mechanical cleanliness were emphasized. It was self-consciously modern and culturally technological. To a larger extent than in cubist painting, which it most closely resembles, recognizable objects appear in purist work. It is two-dimensional, frankly decorative, and constructed on the basis of an elaborate, systematic color theory. Le Corbusier, after 1921, applied the same "machine-age" aesthetic to his architecture, for which the purist paintings were decoratively well adapted. From 1920 to 1925 Ozenfant and Jeanneret edited a magazine in defense of their doctrine, called *L'Esprit Nouveau*. See FRENCH ART. —L.D.L.

**purity.** This term has one general meaning in criticism: that a work pursues and exhibits the one true artistic value, and neglects all spurious values. As is to be expected, it has as many special meanings as there are special schools of criticism. Each group calls *pure* those works which seem to it to fulfill the nature and function of literary art. Recently, the term has been the most frequently used to indicate literary work in which the values of sound and structure have been emphasized, and those of meaning and reference neglected. Here, music is regarded as the most *pure* of the arts, because it can rely upon only the artistic values of the formal organization of sound, and can obtrude all extraneous values. Then, literary art is regarded as *pure* to the extent that it approaches music as a strictly formal art. —I.J.

**quadrille.** A dance in 5 movements or figures.

**quadrivium.** The *trivium*, grammar, logic and rhetoric, and the *quadrivium*, geometry, astronomy, arithmetic and music made up the 7 liberal arts in the medieval curriculum. Music, the 4th branch of the quadrivium was zealously cultivated in medieval universities. For its theory the treatise of Boethius (c. 480-524) *De Institutione Musica* was studied. Boethius' 3 divisions of music are characteristic of medieval thought and with slight variations were adopted by later writers. (1) *Musica mundana* included the music of the revolutions of celestial bodies, a concept borrowed from the Pythagorians. (2) *Musica humana*: "Human music", he states, "is that which is understood by anyone who descends into himself or enters into himself". This concept rejects the testimony of the ear (*"relicto aurium judicio"*) in the investigation of music and proclaims the superiority of theory over practice. (3) *Musica instruments constituta* is sensuously perceptible and includes both that of the voice and instruments. It stands to (1) and (2) in the same relation that Plato's world of individuals does to the Ideal world. —V.A.

**quadruplet.** A group of 4 equal notes performed in the time of 3 or 6 of the same kind.

**quail.** See SYMBOLISM IN FAR EASTERN ART.

**quality of a dance movement.** Refers to some essential property which characterizes a dance movement and distinguishes it from other movements.

Since the essential characteristics of motor sensations by which movement is known and judged are time and stress, it follows that the source of the distinguishing qualities must lie in the particular rhythmic structure of actions and in the degree of tension present in their execution. Many of the body's actions establish their own time and stress phases by the very law of their functioning. Out of these innate motor responses have evolved a meaning and an appreciation of their characteristic forms and qualities. Especially is this true of swinging movements. Most of the large movements of the body are pendular because of the hinged character of its construction. Consequently swinging action is of necessity a structural characteristic that is dominant in all movement. Therefore its rhythmic form is by nature established in the neuro-muscular system and furnishes the source of study for all other rhythmic structures. Swinging pendular action by nature of our behavior equipment must be considered as the primary form from which all other movements are derived by a modification in its proportionate time and stress values.

On the basis of all movement being derived from an original swinging form, the following list is suggested as modifications of it: swinging, sustained, flowing, percussive, vibratory and syncopated.

The free, *swinging pendular* movements are characterized by a rhythmical to and fro action having passive acceleration and retardation as experienced when swinging in a swing. The end of each phase is marked by a momentary pause which continues until momentum is overcome by the force of gravity, per-
